Perceived failures of centralization have contributed to interest in decentralization of natural resource management. Local decision makers were assumed to have a better sense of local resource conditions, a better understanding of how local natural resource systems respond to various interventions, and a better capacity to enforce management rules.^[3,4,8] Even under favorable conditions, local decision makers do not always have a full understanding of interactions within natural resource systems, particularly over longer periods of time. Moreover, the effectiveness of decentralization depends on a minimal degree of local consensus about

the nature of the management problem and how it should be addressed, supported by legitimate authority to make and enforce decisions about natural resource management. As discussed in the next section, these conditions do not always obtain.

INTERDEPENDENCIES AND JURISDICTIONS

Management of many natural resources involves interdependent decision making. Unless coordinated, the decisions by one actor or jurisdiction may undermine the effectiveness of decisions by others or simply shift problems from one location to another. Or actors may reject an otherwise acceptable policy because the benefits will be shared with others who are perceived as not doing their fair share. The interdependent nature of natural resource systems creates collective action problems. Because interdependency often spans jurisdictions, it also challenges their delineation.

Collective action is hindered by coordination problems or the threat of free riding. The nature of the resource influences the kind of collective action problems that emerge. As illustrated in Fig. 1, resources (or economic “goods”) may be characterized along two dimensions: subtractibility and ease of exclusion. Subtractibility, also referred to as rivalry in consumption, indicates that use of the resource by one actor reduces its availability for use by others. Resource use encompasses non-subtractible consumption (e.g., viewing a sunset) as well as subtractible consumption (e.g., fishing). Subtractible goods present problems of depletion; non-subtractible goods cannot be depleted, by definition, but their value may be lowered through crowding. Ease of exclusion depends in part on the physical nature of the resource and technologies that influence the capacity to monitor use. Combinations of these two dimensions yield a fourfold classification: Private goods are subtractible but exclusion is easy; club or toll goods are non-subtractible goods for which exclusion is easy; common pool resources or goods combine difficult exclusion with subtractibility; and public goods feature difficult exclusion and non-subtractibility.

Externalities—side-effects of actions that affect somebody other than the actor—represent an important

	Exclusion easy	Exclusion difficult or costly
Subtractible (rivalrous in consumption)	Private goods	Common-pool goods
Non-subtractible (non-rivalrous in consumption)	Club or toll goods	Pure public goods

Fig. 1 Types of goods.

subtype of non-excludable good. Externalities may be positive, as when tree planting on a hillside improves water quality at the foot of the hill, or negative, as when water pollution affects people downstream. Positive public goods, common pool resources, and externalities tend to be undersupplied because the producer does not enjoy the full benefits; negative public goods, common pool resources, and externalities tend to be over-supplied.

When exclusion is easy, resource management requires the design of institutions to reinforce exclusion and limit either extraction or access. When exclusion is not easy, resource management must address free riding as well as levels of use or access.

Natural resource policies that build on ease of exclusion seek to match the boundaries of rights and responsibilities to the boundaries of the resource system. In essence, these policies redefine property rights within jurisdictions or create new jurisdictions. Thus, privatization is supposed to reduce land degradation by ensuring that the land owner bears the full cost of land use, whether in the form of grazing pressure, timber production, or the sustainability of agricultural techniques. The same premise lies behind the creation of special jurisdictions for the management of river basins and aquifers that overlap with several subnational or national political jurisdictions. Pricing policies also involve the formalization and redefinition of rights and responsibilities for resources and the consequences of actions that were not previously priced. The creation of new formal rights and associated markets for those rights can be seen in carbon markets and similar programs.

Appealing in the abstract, institutional solutions can run into fatal political problems. Alterations to property rights within a single jurisdiction have distributional implications that may hinder otherwise desirable reforms. Natural resource systems encompass a variety of resources that are used or valued by different individuals and groups in different combinations and in different ways. Subsistence and commercial users of forests, for example, value different tree species and give different priority to trees and non-timber resources. Others value forests for their influence on the water table, soil conservation, habitat protection, or for their very existence. To take another example, cattle may be raised for beef markets or kept for ploughing, for milk, or as a store of wealth. The complexity of natural resource systems complicates policy making not only because these systems are difficult to understand, but also because policy choices often have significant distributional consequences.

Different management goals suggest different management strategies. Policies that promote particular management strategies favor some interests and values over others. Although the well-to-do may enjoy

more influence over policy-making processes, problems of exclusion limit the enforceability of institutions that ignore opposing interests. Institutional solutions also become more difficult when they compete with or attempt to displace prior institutions, as discussed below.

Coordination problems arise when multiple solutions exist and solutions have different distributional implications or actors lack a mechanism for selecting the same solution. Unless communication is a problem (e.g., among pastoralists or other mobile populations), distributional conflict is more likely to obstruct coordination.

Free riding becomes a problem when exclusion is difficult. Although everybody might benefit from provision and maintenance of public goods, each actor would prefer to enjoy benefits without bearing the costs of the public good. Likewise, even if nobody wants common pool resources to be depleted, each actor would prefer others to bear the costs of preserving the resource. Within a single jurisdiction, individuals or households may face free-riding problems in managing a common water source, forest, grazing area, park, or other such resource. When common pool resources cross jurisdictional boundaries, incentives to free ride influence the behavior of jurisdictions and their officials as well as the individuals within each jurisdiction. Thus, countries that share a river basin or forest might wish to limit overall consumption yet resist restrictions on their own use. Even if the respective governments agreed on a formula for distributing limitations on use, the limitations might not be strict enough to sustain the resource system. Moreover, precisely because exclusion is difficult, governments may be unable to effectively restrict resource use by individuals and firms even if they agree to do so.

Institutional design can compensate for problems of exclusion, if reliable monitoring and enforcement of rules restricting access to and use of common pool resources can be achieved.^[9] Cohesive social relations, high levels of trust, and common interests in the shared resource facilitate effective monitoring and enforcement. Conversely, divergent understandings of the resource system, competing interests in the shared resource, and poorly coordinated or competing institutional arrangements exacerbate difficulties in exclusion. Problems of divergent understandings and interests may arise among local resource users or between jurisdictions. When jurisdictions are territorially nested (e.g., a locality in a region in a country), coordination across the various levels determines whether the jurisdictions reinforce or undermine management strategies at each level.^[3] Free riding by jurisdictions as well as coordination problems must be addressed when resources cross jurisdictional boundaries.

Special-purpose jurisdictions dedicated to natural resource management have been proposed for various resources, including aquifers, river basins, watersheds, forests, and wilderness areas. Where general-purpose jurisdictions reflect administrative, historical, or cultural boundaries, special-purpose jurisdictions attempt to encompass an entire resource system.^[10] The performance of special-purpose jurisdictions depends on relations with general-purpose jurisdictions with which they overlap but rarely coincide. When special-purpose jurisdictions are created by officials of general-purpose jurisdictions frustrated with their inability to manage shared natural resource systems, the two sets of jurisdictions are likely to reinforce each other. An example might be a river basin commission consisting of national governments. Whether the special-purpose jurisdiction adopts a sustainable management regime depends on bargaining among members. The threat of sabotaging implementation strengthens the position of each member, limiting the scope for acceptable policies but decreasing the probability of coordination or free-riding problems.

When special-purpose jurisdictions coexist with other authorities that have no input into their creation or operation, competition between jurisdictions can interfere with resource management. Donor agencies and national governments have created special-purpose committees for community-based natural resource management, for example, without involving local or regional authorities. Indeed, the creation of new special-purpose committees sometimes attempts to circumvent government bodies that are perceived as inefficient, corrupt, insufficiently committed to sustainability, or otherwise limited in their capacity for resource management.^[11] Officials associated with general-purpose authorities frequently view special-purpose committees with overlapping jurisdictions as competitors. The ability of special-purpose jurisdictions to achieve anything at all depends not only on dynamics of internal decision making, but also on the authority and legitimacy of competing institutions and the level of hostility between institutions. Authority and legitimacy flow from both formal and informal institutions and resources, limiting the capacity of donors and national decision makers to overcome local antagonism through the introduction of new formal institutions.

CONCLUSIONS

Several features of natural resources exacerbate more general policy-making challenges. Complex interactions within natural resource systems interact with organizational behavior to limit the capacity of policy makers to detect resource degradation before it becomes

severe. The complexity of natural resource systems also increases the cognitive challenges of developing appropriate policies for sustainable resource management. Shortcuts in decision making and action that deal with cognitive limitations become more costly because changes in natural resource systems may be irreversible. When scientific experts are brought in to help address cognitive challenges, the degree of complexity in natural resource systems exacerbates more general problems of democratic accountability in situations involving delegation of authority. Spatial and temporal variation in natural resource conditions further challenges centralized policy making and limits the effectiveness of standardized policies. Efforts to address variability in resource conditions require either highly detailed policies or decentralization of authority. Highly detailed policies further aggravate cognitive challenges, while decentralization will not occur unless policy makers give up some of their own authority.

Natural resources vary in degree of subtractibility and the difficulty of exclusion. Different combinations of these features present different types of challenges for making and implementing natural resource policy. When exclusion is not a problem, policies can focus on management of extraction levels. Debate will center on management goals, the appropriate level of overall extraction, and related distributional issues. When exclusion is a problem, policy must address monitoring and enforcement problems as well as management goals and extraction levels. Both coordination and free-riding problems must be addressed. These issues play out among individual resource users, between overlapping jurisdictions, and between political jurisdictions and resource users.

Naturalistic Decision Making

Anna C. Goldoff

*Department of Public Management, John Jay College of Criminal Justice,
New York, New York, U.S.A.*

INTRODUCTION

This article details an important new addition to decision-making theory and practice, the model known as “naturalistic decision making.” Naturalistic decision making (NDM) is the study of real people making crisis decisions. Its focus is on the use and usefulness of experience in making complex decisions in uncertain and constantly shifting environments.

Naturalistic decision making emphasizes the highly rated consequences, time pressures, lack of information, and incomplete goals that characterize most political, administrative, and public policy environments.^[1] It is deeply rooted in classical works in decision theory, political science, and public administration, especially in works done by Charles Lindblom and Herbert Simon.^[2,3] Its most prominent proponent today is the researcher Gary Klein, who reformulates NDM into his own Recognition-Primed Decision Model.^[4]

Naturalistic decision making is said to be the representation of a true paradigm shift in decision theory away from the scientific/classical/rational approach. This article defines naturalistic decision making; elaborates on its roots in political science and the public administration literature; and demonstrates how it fits into a new paradigm of decision-making theory. This new paradigm has evolved as an organic alternative to the classic linear rational model of economic theory.

Detailed elements and analysis of the naturalistic decision-making model will be offered here, along with new directions in the field and recommendations for its practical implications and implementation. This article ends with a summarizing note and conclusion on the impact and importance of naturalistic decision making.

OVERVIEW

Naturalistic decision making summarizes a paradigm shift in decision-making theory, veering the field far away from the classical ideal, the rational-comprehensive (or rational actor model) or analytical decision-making model (ADM).^[5] The rational model (based on economic “choice” theory) thrives in controlled, laboratory-like settings with fixed, concurrent alternatives. It stresses unlimited time and resources

in order to choose a “right” answer or choice.^[6] Cost-benefit analyses, probability theory, and decision trees are all used by the decision maker to find a correct policy or administrative action.

Since the 1970s, cognitive psychologists, political scientists, and policy analysts have been criticizing rational choice as the ideal method for politicians and public administrators to follow.^[7] Building on Barnard’s and Simon’s work^[8] on more realistic decision making in large organizations, the field of naturalistic decision making has been born.^[1] It incorporates attributes of incremental theory (Lindblom) and of Simon’s bounded rationality^[2] (to be discussed in more detail below).

Naturalistic decision making has been built on empirical studies of how real people in crisis decisions really make decisions.^[4] It emphasizes the roles played by experience, intuition, quick assessments, and expert judgment, rather than time-consuming formulas and decision trees. It is based on the idea that time is of the essence in most political and public policy decision making. Aspects of the model also emphasize the important roles played by training and the case study method in improving managerial capacities to decide successfully.^[9] Thus, it has profound theoretical and practical (technical) consequences for the field of decision analysis.

Recommendations from the naturalistic decision-making researchers also fit into the notion that a paradigm shift has occurred—that a so-called “New Paradigm” has emerged to counter the rational approach as a decision-making ideal.^[10] This new paradigm embraces change rather than runs away from it; is organic (one with its environment); recognizes pattern recognition and deduction (looking at the whole or big picture); moves decision makers away from “tunnel vision.” It accepts quantitative tools and fact-based models like risk analysis and strategic management but says that they are alternative tools, not substitutes for the intuition, experience, and judgment of a skilled manager or leader.

This new paradigm (of which naturalistic decision making is a part) fits in more with fluid, flatter, task force or task-based organizations that are harder to manage than the old bureaucratic, “chain of command” hierarchical entities (Weber).^[11] As government, the

private sector, and non-profit organizations try to adapt to fast-paced technological, informational, political, and environmental changes, they will be pressed to adopt the naturalistic decision-making model. Their decisions have more costly impacts, and the time and resources they have to make them in have been telescoped. So, a model that emphasizes fast-paced, crisis decision-making and which is based on concrete, provable training methods to improve decision makers should be much in demand.

THEORETICAL BACKGROUND/HISTORY

Naturalistic decision-making as a model of decision analysis arises out of a simple bifurcation in political science and public administration theory, what Lindblom calls the “root versus branch” theory of policy making in his classic essay, “The Science of ‘Muddling Through’.”^[12] Graham T. Allison calls the classical model of crisis decision making the “rational actor” approach, used by the analyst when he structures decisions or events as the purposive choices of consistent actors (the root method).^[12] He says that “Classical ‘economic man’ and the rational man of modern statistical decision theory and game theory make optimal choices in narrowly constrained, neatly defined situations.”^[12] He says that, “In economics, to choose rationally is to select the most efficient alternative, i.e., the alternative that maximizes output for a given input or minimizes input for a given output.”^[12] The rational decision maker faces a given problem and has a given set of alternatives and consequences from which to choose.^[12] The simple rational solution is to “select the alternative whose consequence is preferred . . . ranking each set of consequences in order of preference.”^[12] Allison sees the basic concept of rational action thus as goals and objectives, alternatives, consequences, and choice.^[12]

Incrementalists say, “whoa,” not so fast. Choice and decision making is not that easy. Instead of maximizing alternatives, real-life decision makers “satisfice” or do “good enough.”^[13] They use decision-making dodges or shortcuts like “the next chance,” “feedback,” “remediality,” “seriality,” and breaking decision-making bottlenecks.^[13] This results in incrementalism, policy-making that:

1. Concentrates the policy maker’s analysis on familiar, better-known experiences.
2. Sharply reduces the number of different alternative policies to be explored.
3. Sharply reduces the number and complexity of factors the policy maker has to analyze.^[13]

Herbert Simon calls this more realistic approach to decision making “bounded rationality” as opposed to

the comprehensive rationality of the classical model. He says that real-life decision makers factor (or split up) complex problems; they satisfice, they search, they are motivated by uncertainty avoidance, and they create organizational repertoires to deal with complex problems.^[12] Thus, Charles Lindblom concludes that “the piecemealing, remedial incrementalist or satisficer may not look like an heroic figure. He is nevertheless a shrewd, resourceful problem-solver who’s wrestling bravely with a universe that he is wise enough to know is too big for him.”^[13] Naturalistic decision making is a natural offshoot of Lindblom’s wise incrementalist. It is an approach that is based on empirical study of real-life crisis decision-makers in many different fields. These key decision makers satisfice rather than maximize alternatives; they use remediality, they try out serial alternatives; they break up bottlenecks; they factor complex problems; and most importantly, they make decisions based on experience, not cost-benefit analysis or the construction of elaborate decision trees. They almost never compare concurrent alternatives. Naturalistic decision making is the twenty-first century progeny of mid-twentieth century incrementalism.

NATURALISTIC DECISION MAKING

In *Designing TDG’s—A Tactical Decision Games Workbook—How We Decide*, the U.S. Marine Corps talked about the “classical (analytical) decision making model (ADM)” and said that for decision making to be rational or systematic, it has to follow the format below:

Concurrent comparison of multiple options (my emphasis) . . . identify all the possible options, analyze all these options, assign a value to each aspect of each option . . . and choose the option with the highest aggregate value . . . this is known as multi-attribute utility analysis.^[14]

This, as previously noted, is Lindblom’s “root” method and H. Simon’s “comprehensive rationality.” It is a method that is time consuming, as doing a complete multiattribute analysis on complicated policy, political, or military crisis decisions is going to take you a lot of time. Time is usually of the essence in crisis situations, and if it is, use of this approach is going to be minimized in time-sensitive, complicated situations.

“The analytical model requires a high level of certainty and accuracy of information.”^[14] If the future is uncertain and the context unknown, and “if information is missing or unreliable . . .”^[14] again, the use of an ADM is inhibited. Third, “reasoning power is essential to analytical decision-making, but *experience and judgment are not* (my emphasis).”^[14] Theoretically, a novice or an expert will come to the same conclusion after subjecting the problem to

the rational-comprehensive process. Intangible factors like “*judgement, intuition and insight*” (my emphasis)^[14] are not necessary and, in fact, are excluded, because they are not quantifiable.

What is naturalistic decision making? As we have seen, classical theory relies on “economic man,” a rational decision maker who maximizes (or optimizes) decisions in carefully controlled, neat and tidy situations. Decisions are made in a closed system, operating in a perfect world, with perfect, “all-seeing” knowledge and unlimited time and resources. Proponents and researchers know that this is not how decisions are made in the real world. Naturalistic decision making offers a contrasting paradigm consisting of:

1. Ill-structured problems (not artificial, well-structured problems).
2. Uncertain, dynamic environments (not static, simulated situations).
3. Shifting, ill-defined, or competing goals (not clear and stable goals).
4. Action/feedback loops (not one-shot decisions).
5. Time stress (as opposed to ample time for tasks).
6. High stakes (not situations devoid of true consequences for the decision maker).
7. Multiple players (as opposed to individual decision making).
8. Organizational goals and norms (as opposed to decision making in a vacuum).^[15]

As mentioned above, Gary Klein is the driving force who pioneered the naturalistic decision making model. In his book, *Sources of Power—How People Made Decisions*,^[4] Dr. Klein sums up 13 years of field studies that debunk the rational model and support, instead, NDM. He says that the rational approach emphasizes human limitations, making it seem as most key decision makers are constantly falling short. Klein says this is not true at all, that his empirical studies of “firefighters . . . pilots, nurses, military leaders, nuclear power plant operators, chess masters . . .”^[4] and others have demonstrated the exact opposite to be true. These studies have relied heavily on interviewing and extensive participant observation by Dr. Klein and his staff. Key, heavily stressed individuals in crisis situations almost never use the rational approach, in the form of raising and evaluating several or many concurrent alternatives.^[4] Key decision makers do not rely on what he calls “conventional sources of power . . . deductive logical thinking, analysis of probabilities, and statistical methods.”^[4] Instead, they use four things—“the power of intuition, mental simulation, metaphor, and storytelling.”^[4] They use these things in a context that is realistic and typical. Klein studied people under time pressure, experienced decision makers who were making high stakes decisions

with inadequate information, unclear goals, and constantly changing conditions and procedures.^[4] Of course, this describes most political or policy decisions as well.

Klein’s team found that in case after case, people do not use the rational approach—they have no time.^[4] They do not use two-option strategies, they “don’t compare anything.”^[4] In studying five commanders at work, he found that they did not “compare options” or “wrestle with choices.”^[4] Instead, when faced with complex, emergency situations, commanders “came up with a good course of action from the start”^[4] based on their experience. Klein stated that “their experience let them identify a reasonable reaction as the first one they considered, so they did not bother thinking of others.”^[4] He called this a skillful use of strategy—“recognition-primed decision-making.”^[4]

Klein’s decision makers tended to evaluate several options, but not concurrently—they did this one at a time. Also, they evaluated and rejected options in a matter of minutes. He related it to Simon’s notion of alternative generation and search, in short, of “satisficing,” as alluded to above.^[4]

To sum up, Klein’s decision makers like Herbert Simon’s did not search to maximize or find the best choice, they just turned up options until one worked.^[4] Also, rather than constructing analytical decision trees, real-life crisis decision makers used mental simulations to discover whether or not their preferred strategies would work.^[4]

Caroline Zsombok looked at themes in NDM research^[1] and found that in the past decade, NDM researchers have focused on the “big picture:” situational assessment and awareness; expertise; and cognitive task analysis.^[1] The latter, she said, “as opposed to behavioral task analysis is to understand the decision requirements . . . behind an experienced person’s job or task performance.”^[1] The impact, implementation, and themes for training decision makers are the topic of the next section.

NEW DIRECTIONS

Naturalistic decision making as a field promises to make better decision makers in large organizational settings. It states that successful crisis decisions are made due to the mature judgement, intuition, and experience of key decision makers. This translates into a focus on expertise. How can training move the novice through several stages of proficiency, to becoming an “expert” in the field? Because situational pattern recognition, mental modeling (simulations), and cognitive task analysis are part of the approach, researchers have focused on the case study approach in training and implementation. Constant repetition of various alternative decision-making problems, under time-stressed

(and incomplete information) conditions is required, much like the experience of a new resident in a hospital emergency room. Soon, the novice develops pattern recognition skills, after seeing the same set of symptoms again and again. Mental simulation of possible “outcomes” (and causes) leads him to develop shortcuts to the best possible solution, under the circumstances. Emergency room physicians do not have the time to develop elaborate alternatives and scenarios. The first and most basic solution to come to mind is usually tried and hopefully works. Cognitive task analysis also emphasizes the sharing of information and intention among decision makers, as timely communications are crucial in many real-life crisis and political and organizational tasks. Also, real-life organizational and public decision making tends to be made by teams, not single individuals. If teams are making the decisions, communications flows are key to making successful decisions. In this way, naturalistic decision making is in sync with other New Paradigm theories like chaos theory.^[16]

Training to improve “naturalistic decision makers” must make use of real-time scenarios and uncertain and dynamic situations (just as in the real world). Decision makers have to be trained to multitask (again, as in the real world, real-life problems do not present themselves one at a time). Immediate “thinking-aloud” verbal expressions of the task just completed can help higher-level managers and researchers to deconstruct actual decision-making processes. Levels of proficiency can be benchmarked through the number of successful solutions gained in these simulations and training sessions. In short, naturalistic decision-making researchers are saying that expertise and intuition can be “taught” or force-fed by constantly facing the decision maker with realistic conditions and constant problems to be solved.

CONCLUSION

Naturalistic decision making is a new field in decision-making theory and practice. It is a theoretical outgrowth of incrementalism and of H. Simon’s concept of “bounded rationality.” Its focus is on real-life decision making that has to take place in uncertain environments that are constantly changing with ill-defined or competing goals. Decision makers are charged to make these decisions under the stress of little time and clouded information, rather than in the perfectly realized world of goals, alternatives, and resources that represent the rational (actor) or choice model. The naturalistic decision maker does not know or cannot predict the future but can use mental simulation to find the best solutions to the problem that will “satisfice” or be good enough.

Naturalistic decision makers also work in teams in large bureaucratic organizations, so theories of individual choice are not as applicable. Decision making is not made in a vacuum but is influenced and effected by a complex environment.

Naturalistic decision-making research has relied heavily on the case study method, participant-observation, and key person interviews in crisis/emergency management-type professions. Its initial conclusions are that more empirical research is needed, but better decision makers can be made through a combination of repetitious and realistic case simulations.

Net Assets and Fund Balance

Dean Michael Mead

Governmental Accounting Standards Board, Norwalk, Connecticut, U.S.A.

INTRODUCTION

Financial position—the status of a government’s assets, liabilities, and residual balances at a given point in time—is undoubtedly a staple of governmental financial analysis. The commonly accepted approach to evaluating financial position is to compare a measure of a government’s residual balances—its *net assets* or *fund balance*—with a measure of its annual financial activity.

Net assets and fund balances, therefore, may be among the most basic and important information reported in a government’s financial statements. This entry explains the nature of net asset and fund balance information and the central role it plays in governmental financial analysis. The first two sections describe the basic requirements under generally accepted accounting principles (GAAP) for state and local governments in the United States for reporting net assets and fund balance. The succeeding section then describes how this information is incorporated by financial analysts into assessments of governmental financial health.

NET ASSETS

State and local governments that prepare their annual external financial reports in conformity with GAAP are required to present four financial statements that could be described as statements of financial position. Three of these financial statements—the *government-wide* and *proprietary funds statements of net assets* and the *statement of fiduciary net assets*—are prepared using an accrual basis of accounting and economic resources measurement focus. This means that these statements report all of a government’s assets, both financial and capital, as well as all of its liabilities, both short term and long term.

In simple terms, net assets are the difference between assets and liabilities. In other words, if a government’s assets were used to repay its liabilities, net assets would be what was left over—they are literally the government’s assets *net* of liabilities. In the private sector, this is called retained earnings or owner’s equity. From a governmental perspective, net assets are resources that the government can use to provide services.

Government-Wide and Proprietary Funds Net Assets

The issuance of GASB Statement No. 34, *Basic Financial Statements—and Management’s Discussion and Analysis—for State and Local Governments*, substantially revised the basic model for financial reporting by subfederal governments in the United States.^[1] Statement 34 added new financial statements, prepared on a full accrual basis for the entire governmental entity, to the existing fund financial statements. One of these new accrual statements, a statement of net assets, reports the assets, liabilities, and net assets of a government. The information in the statement is typically presented in four columns: information related to *governmental activities* (typical governmental services supported primarily by taxes and other general revenues); *business-type activities* or BTAs (those services operated like private enterprises, charging fees intended to recover costs); the *total primary government* (governmental and business-type combined); and *discretely presented component units* (public benefit corporations and other legally separate entities for which the primary government is financially accountable) (see [Table 1](#)).

A unique feature of governmental accounting is its combination of consolidated information for the government as a whole and disaggregated information for specific portions of the government. These individual portions or *funds* are reported in three groups of financial statements: *governmental funds*; *enterprise funds*; and *fiduciary funds*. The proprietary funds are reported using the same full accrual accounting as the government-wide statements. Proprietary funds include *enterprise funds*, which are largely synonymous with BTAs, and *internal service funds*, which track the finances of activities that provide services to the government itself, such as a central garage or supply function. The proprietary funds financial statements show the *major* or the most significant enterprise funds separately and aggregate the remaining funds in a single column.

Net assets are reported in three categories at both the government-wide level and for the proprietary funds—*invested in capital assets net of related debt*, *restricted*, and *unrestricted*. The title of the first category is self-explanatory: the net book value of a government’s long-lived assets (i.e., the original cost

Table 1 Sample net assets section from a government-wide statement of net assets

Net assets	Primary government			Component units
	Governmental activities	Business-type activities	Total	
Invested in capital assets, net of related debt	\$123,456,789	\$76,543,210	\$199,999,999	\$15,151,151
Restricted for:				
Capital projects	34,567,890	—	34,567,890	4,343,343
Debt repayment	2,345,678	4,321,098	6,666,776	—
Recreation programs	5,678,901	—	5,678,901	—
Other purposes	1,234,567	2,109,876	3,344,443	—
Unrestricted	3,456,789	10,987,654	14,444,443	1,212,212
Total net assets	\$170,740,614	\$93,961,838	\$264,702,452	\$20,706,706

less accumulated depreciation) minus outstanding debt used to finance the purchase, construction, or rehabilitation of those assets. This feature of residual balance reporting is unique among accounting standards, signaling the importance of capital assets, particularly infrastructure assets such as roads and sewer pipes, in the provision of governmental services.

Restricted net assets represent resources that are legally limited to a particular purpose. Net assets can be restricted in three ways:

- By external parties, such as other governments, donors, or grantors.
- By constitutional provisions.
- By enabling legislation.

Enabling legislation, as it is used in Statement 34, is not run-of-the-mill legislation. Statement 34 specifically requires that it must authorize the government to raise an entirely new revenue source and bind it to a particular purpose with a legally enforceable restriction, rather than *earmark* existing resources. This feature is also unique to state and local governments. In designing it, the GASB viewed these characteristics of enabling legislation as constituting “an unbreakable compact with the resource providers that the resources would be used for the promised purpose only.” (See, paragraph 18 of Ref.^[2].) In other words, the government may not have been able to obtain the tacit agreement of the taxpayers to raise these resources if it did not promise to use them in a manner acceptable to the taxpayers. Furthermore, these taxpayers or others external to the government have the power to compel the government to use the resources only for the purposes specified in the enabling legislation.

Unrestricted net assets are all of the resources not in one of the other two categories. These resources can be used by a government for any purpose. A government

may disclose in the notes to the financial statements that it has tentative plans regarding how it will use its unrestricted resources, but it is not allowed to display such *designations* on the face of the statement.

Lastly, if a government’s net assets include resources from permanent endowments or permanent fund principal amounts, then a further distinction is made between net assets that are *expendable* and *non-expendable*. Nonexpendable resources are required to be retained in perpetuity—they can be invested and the earnings spent, but the nonexpendable resources themselves cannot be spent.

Fiduciary Net Assets

The fiduciary funds track activities in which a government acts as a fiduciary for resources that belong to other organizations or persons. Unlike the governmental and proprietary funds, fiduciary fund finances do not appear in the government-wide financial statements because these resources do not belong to the government and cannot be used to provide services. The most common example of a fiduciary fund is a *pension trust*. They also include *private-purpose trusts*, *investment trusts*, and *agency funds*.

The fiduciary funds do not use the three categories of net assets described above. Rather, the difference between plan assets and plan liabilities is captioned *net assets held in trust for pension benefits* or other purposes. Agency funds, which hold resources temporarily before they are distributed to other governments or persons and organizations external to the government, show no net assets at all. The assets of agency funds are exactly equal to the amount that must be passed along. Agency funds are often used when a government collects taxes on behalf of other governments; the receipts are held in the agency fund

until they are disbursed to the various governments, but at no time do those resources belong to or are available to the government collecting them.

FUND BALANCE

The aforementioned accounting and reporting takes place in a full accrual environment. The governmental funds, however, utilize a *modified accrual accounting basis* and *current financial resources measurement focus*. As a result, these funds (which are roughly synonymous with the governmental activities of the government-wide statements) focus on the short-term finances of the government—essentially, the year following the date of the financial statements. The governmental funds include the *general fund* or primary operating fund, *special revenue funds* (which track resources legally restricted to particular purposes), *debt service funds*, *capital projects funds*, and *permanent funds*. As with proprietary funds, the governmental funds statements show the most significant funds individually in their own columns and aggregate the remaining funds into a single column (see Table 2).

The counterpart to the statement of net assets—the governmental funds balance sheet—includes only current financial resources. These include cash and other assets expected to be liquidated within a year, and liabilities that are expected to be satisfied within a year. There are no long-term investments or capital assets; neither are there any long-term debts. The difference between assets and liabilities in the balance sheet is *fund balance*.

The focus of fund balance is on *availability* of resources. It is of particular interest to finance officers, legislators, and service advocates seeking to allocate resources to areas of need and favored projects. In

addition to new revenues raised during the year, expenditures can be financed with available resources that have been accumulated from prior years. Fund balance communicates the amount of resources available and the purposes for which they are available to be used.

Fund balance is reported in two components, reserved and unreserved. Two factors may result in a reservation of fund balance. First, resources may be in a nonexpendable form, such as inventory. Second, resources that have been “legally segregated for a specific purpose” are reported as reserved fund balance. Legal segregation includes the circumstances that lead to a restriction of net assets, but is broader: There are actions that would reserve fund balance, such as legislative earmarking, but would not restrict net assets.

It is important to note that the second kind of reservation interacts with fund reporting, which is intended to demonstrate that resources are limited to or intended to be used for a specific purpose. In the general fund, any legal limitation on the use of resources will be shown as a reservation of fund balance. However, the other governmental funds already communicate that the resources they contain are intended for a particular use. The resources in a debt service fund, for example, are supposed to be used to repay debt. Therefore, in order for a legal segregation to result in reserved fund balance in one of the other governmental funds, it must be for a purpose that is *more specific than the purpose of the fund itself*. For instance, if a government has resources that can only be used to rehabilitate school buildings, these resources could be shown as “reserved for school construction” (or a similar title) in a broad capital projects fund. However, if the government put these resources in a “school construction fund,” they would not be shown as reserved because they are not legally segregated from the other resources of *that fund*, all of which are there for school construction.

Table 2 Sample fund balance section from a governmental funds balance sheet

	General	Housing programs	Economic development	Other governmental funds	Total governmental funds
Fund balances:					
Reserved for:					
Inventories	111,111	—	—	8,888	119,999
Encumbrances	666,666	33,333	7,777	2,323,323	3,031,099
Debt service	—	—	99,999	—	99,999
Other uses	222,222	—	100,000	1,454,454	1,776,676
Unreserved, reported in:					
General fund	444,444				444,444
Special revenue funds		1,555,555		1,333,333	2,888,888
Capital projects funds			10,101,101	2,444,444	12,545,545
Total fund balances	\$1,444,443	\$1,588,888	\$10,308,877	\$7,564,442	\$20,906,650

Unreserved fund balance represents all resources that are not reserved and thus can be used for any purpose. Governments have the option of *designating* a portion of their unreserved fund balance in order to communicate what they *intend* to do with the resources. Actual practice varies widely. Roughly half of state and local governments report designations, primarily on the face of the balance sheet; a relatively small percentage of governments report their designations in the notes to the financial statements.^[3,4]

Information about designations is highly important to many financial statement users. Some users review individual designations of unreserved fund balance to determine which of a government's designations, based on experience, are likely to be used as identified in the balance sheet and which the users believe could be applied to any purpose. Thereby, these users construct an unreserved–undesignated fund balance amount that they use in their financial position ratios.

Designations, however, are highly problematic. Because they generally have no legal backing, but are merely statements of intent, there is no guarantee that a government will use those resources as it stated. The government is free to change its mind at any time. Second, because many governments do not report designations in their balance sheets, comparability problems arise; it may not be safe to assume that governments that do not report designations have not, in fact, identified intended purposes for their unreserved fund balances.

Third, many governments categorize their designations in a manner that communicates very little information to the financial statement user. For example, it is common for governments to designate unreserved fund balance for “future expenditures” or “subsequent years’ budgets.” These are meaningless titles, because all designations—in fact, all fund balance that is in an expendable form—are intended to be expended at some time in the future. Fund balance is, by definition, resources available for use in providing services or operating a government.

USING NET ASSETS AND FUND BALANCE INFORMATION TO ANALYZE FINANCIAL POSITION

Financial or operating position is likely the most common element of paradigms for analyzing the financial health of governments. Every major paradigm includes financial position or a similar term as a major component. For instance, it is one of the six basic financial factors affecting financial condition identified in the International City/County Management Association's financial analysis text.^[5] The “10-point test,” which is widely used by local governments to gauge their

finances, includes three ratios for measuring financial position.^[6] It is accorded similar prominence by Ives and Schanzenbach,^[7] Mead,^[8] Berne and Schramm,^[9] and Chaney, Schermann, and Mead.^[10] A review of the governmental financial analysis literature identified financial position as one of six major factors widely considered, along with surpluses and deficits, revenues and revenue base, expenditures/expenses and spending pressures, outstanding debt and debt service, pensions and other postemployment benefits, and liquidity.^[11]

Financial position is typically assessed with the use of ratios that divide net assets or fund balance by a measure of a government's annual financial activity or its aggregate financial size. There is considerable variation in what information analysts actually select for the numerator and denominator of that ratio, however, depending upon their particular interests and the types of governments they are examining. For example, some use total fund balance and others only unreserved or unreserved–undesignated fund balance. Similarly, total net assets or unrestricted may be employed. Furthermore, fund balance for the total governmental funds may be used, or only for the general fund or a combination of other funds. Likewise, some ratios include net assets for the primary government, and other just for the governmental activities or BTAs.

The denominator is either a flow indicator (revenues, expenses, expenditures) or, to a lesser extent, a stock indicator (such as assets or liabilities). Occasionally, a particular portion of revenues, expenditures, or expenses is utilized, such as operating revenues or operating expenses. In any case, the flow or stock information matches the scope of the fund balance or net assets information (total governmental funds, governmental activities, and so on).

A typical financial position ratio using net assets information from Table 1 might look as follows (the denominator amount would come from the government-wide statement of activities):

$$\left(\frac{\text{total primary government unrestricted net assets/}}{\text{total primary government revenues}} \right) \times 100$$

$$\text{e.g., } (264,702,452/6,000,000,000) \times 100 = 4.41\%$$

A typical financial position ratio using fund balance information from Table 2 might look as follows (the denominator amount would come from the governmental funds statement of revenues, expenditures, and changes in fund balances):

$$\left(\frac{\text{general fund unreserved fund balance/}}{\text{total general fund operating revenues}} \right) \times 100$$

$$\text{e.g., } (444,444/12,000,000) \times 100 = 3.70\%$$

Net asset information for the primary government is so new that rules of thumb or benchmarks have not yet been developed against which a net asset ratio can be judged. Regarding fund balance, the Government Finance Officers Association^[12] recommends that governments maintain a general fund unreserved balance of at least 5–15% of general fund operating revenues. By this standard, the fictional government in Table 2 would be deemed to have an undersized fund balance, *ceteris paribus*.

Analysts are aided in their assessment by schedules with 10-year trends in fund balance and net assets. Governments that publish their financial statements in a comprehensive annual financial report include such schedules for the most recent 10 fiscal years in the statistical section.^[13] The statistical section also includes 10-year schedules of changes in net assets and changes in fund balances, thus providing the information needed for the denominator. Analysts can analyze trends in financial position ratios, using these schedules, to determine not only a government's present financial position, but also whether its financial position has improved or deteriorated and to what degree.

CONCLUSIONS

Net assets and fund balance are two kinds of information state and local governments report in their financial statements that communicate the resources governments have that can be used to provide services. Net assets, a full accrual accounting construct, are the economic resources a government can employ in the provision of services and the operations of the government. Under modified accrual in the governmental funds, fund balance reports the current financial resources that a government has available to use. Net assets and fund balance each describe the resources that can be used for any purpose and those that are limited to specific uses.

When divided by indicators of annual financial activity, such as revenues, expenses, and expenditures, net assets and fund balances create ratios that inform the concept of financial position. Financial position—a government's financial standing at a given point in time—is one of the most commonly analyzed and most widely agreed upon elements of the financial health of

governments. Thereby, both net assets and fund balance are undoubtedly among the most crucial information needed for the financial analysis of governments.

Networks, Organizational

Seok-Eun Kim

Department of Political Science, Kansas State University,
Manhattan, Kansas, U.S.A.

INTRODUCTION

The notion of network has become increasingly popular across disciplines. Political scientists conceptualize the complex interactions of multiple actors in the collective policy-making process as *issue networks*, organization theorists view patterned interconnectednesses of organizational systems as *networks*, and sociologists characterize complex social relations that exist among individual interactions as *networks or systems of networks*. In addition to the popularity in academics, the notion of the network is close to our daily life. For example, we often encounter a complex array of interconnected information-sharing systems such as local area network and wide area network. A group of television stations linked by wire and other relays provides another such example.

The proliferation of network usages rests on diverse theoretical foundations, which risk the term meaning so much to so many that it has little specific meaning to anyone. For example, “network” derives impetus from pluralism in political science, resource-dependence theory in sociology, and transaction costs in economics. Different scholars have treated networks differently, using such similar terms as issue network, policy network, policy subsystem, and policy community. In common, all these variants reject a simple process of formulating and implementing public policy and suggest new forms of governance that are neither formal hierarchy, perfect market, oligopoly, nor monopoly.

CONCEPTUALIZING NETWORKS

Despite the popularity of the notion, but in part because of that popularity, the meaning of network is still ill defined and often precludes advancement as a coherent theory. Nonetheless, hope exists, as in the work of O'Toole,^[1] who views networks as “structures of interdependence involving multiple organizations or parts thereof, where one unit is not merely the formal subordinate of the others in some larger hierarchical arrangement” (p. 45). In public administration, networks are considered as complex policy settings in which multiple actors interact to ensure that policy outcomes will suit their interests.^[2] According to these

definitions, networks have four features: 1) resource interdependence between actors; 2) involvement of multiple actors, each with their own interests; 3) lateral or horizontal patterns of exchange; and 4) unlimited territory.

These four features are usefully even if briefly, discussed. First, networks exist inasmuch as actors are interdependent in the policy process. The primary motive for interdependence is to obtain the necessary resources—such resources as people, information, and professional knowledge—to implement specific policies because individual actors are limited in terms of their resources and capacities to act. Hjern and Porter^[3] made it clear that “no single, comprehensive organization can command all the needed resources” (p. 214). Accordingly, network performance relies heavily on the ability of everyday organizations to create and to exploit essential resources with which organizations can manipulate environmental challenges for program success.

Second, networks consist of multiple actors, each with their own interests.^[2] In networks, government instrumentalities can become one or even several of the many actors. Complex public programs have increasingly been carried out in a mixture of public, private, and quasigovernment organizations, with the number of actors involved varying over time. Such combinations clearly require basic changes in the ways “implementation” is characterized. The single agency has served as the unit of analysis in much of traditional public administration. The unit of analysis increasingly has widened into three major classes of actors—executive bureaus, congressional committees, and interest group clienteles—in the classic “iron triangle.” However, Hecla^[4] advised against assuming a stable pattern of interaction. He warns that the closed system thought encouraged by the iron triangle tends to disguise fairly open networks where multiple actors increasingly impinge upon a protean “government.” From extensive search processes, for example, Laumann, Heinz, Nelson, and Salisbury^[5] identified at least 80 major corporate actors, each involved in the four U.S. national policy networks—agriculture, energy, health, and labor.

Third, networks are characterized by lateral or horizontal, not exclusively vertical, patterns of exchange.^[6]

Networks consequently reject both formal hierarchy and the perfect market, falling somewhere in or even beyond the alleged continuum between them.^[1] Actors in networks resist the hierarchical decision-making process in which federal government serves as the authoritative ruler, and in which lower levels of government, citizens, and private participants are considered more or less passive objects of networked interactions. The basic assumption behind the notion of networks is that actors, who possess relatively equal power, exchange their resources and information when they perceive mutual benefit from the interactions. However, influences of specific exchange may vary, depending on who occupies a better position in the network in terms of resources and information.^[2]

Fourth, the territories of networks seem unlimited. Networks exist worldwide, nationwide, regionally, and at local levels of decision events.^[6] Networks also take place among public, private, and quasigovernment organizations. For example, the U.S. government has long history in which private and non-profit providers actually take responsibility for provision of many public programs. Recently, in addition, international networks have been established in response to a growing dispersion of the resources and the limited capacities of a nation to deal with policy problems spanning across countries, such as environmental pollution and oil crises.

IMPORTANCE OF NETWORKS IN PUBLIC ADMINISTRATION

The growing importance of networks in public administration is no accident. Indeed, numerous reasons support the popularity and significance of the new form of governance. O'Toole^[1] declared that "complex networks are not only relatively common, they are also likely to increase in number and importance" (p. 46). In fact, O'Toole pointed out that the importance of networks is inescapable, not only because intergovernmental programs make up a sizable proportion of total government activities, but also because subtle arrays of collective interactions have considerably increased as evidenced, for example, by the expansion of quasigovernmental arrangements.

In addition, increasing reliance on forms of intergovernmental programs is a necessary by-product as policy problems become more "wicked" in such critical areas as health care, housing, and education.^[1] These policies are "wicked" because they are hardly manageable by single organizations; rather, they require network structures where complex issues must be coped with using a multitude of resources provided by many individual and collective actors. Indeed, scholars in policy implementation argue that basically

no program is fully implemented by a single organization. A complex pattern of multiple actors characterizes all implementation structures.^[3]

"Network" notions are also significant because they replace simplistic models. The development of network structures is a reaction to classical administrative systems in which politically neutral hierarchies are said to implement government will in an efficient manner. One major force for breaking the machine-like model came from American pluralism, a value respecting participation of various organized groups in the policy process. This pluralistic value has evolved in accordance with political pressures for maintaining "small government" and adding more organized groups in the policy process to protect representative or democratic systems of governance. For instance, the growing reliance on contracting out the provision of government service delivery proposes that government must remain as small as possible and should provide opportunities for others to maintain or improve the quality of public services.

The growing incidence of cross-cutting mandates provides another reason why networks have proliferated in government.^[1] The layers of mandates impose the same rules on many different programs in various agencies, thereby requiring multiple points of perspective to implement any policy in a consistent manner. For instance, environmental rules not only apply to all levels of governments, but also to various public policies, such as environmental protection, energy conservation, and national security. A necessary outcome is the establishment of networks in response to increasing demand for cooperation.

EFFECTIVENESS OF NETWORKS

The debates on network effectiveness are inconclusive. Earlier, networks typically were viewed negatively, especially in the iron triangle where actors in the policy process collaborate for their own benefit, which threatens democratic legitimacy of government performance (e.g., Ref.^[7]). Relatedly, scholars specializing in game theory view actors as rational utility maximizers who attempt to make strategic alliances with partners in networks to induce maximum benefits for their own.^[8] In policy settings where defecting is a dominant choice among actors, consensus requires high coordination costs to maintain network stability. For example, O'Toole^[9] noticed that the lack of coordination in the central government caused the implementation failure of an air pollution control network in Hungary. Scholars in public management also observe many limitations in networks of public-private collaboration. A web of public, private, and quasigovernment organizations diffuses responsibility, thereby

creating a lack of accountability in many of the important public deliveries of services.

Despite their limitations, there is a growing agreement among scholars that networks have become an important feature of modern public policy and administration. This evaluation gets impressive support in recent sources (e.g., Ref.^[10]). Overall, that is to say, networks work well in situations where policy resources are dispersed and where a given policy structure implies high interdependencies. Networks also lubricate the dissemination of information, thereby increasing learning opportunity and allowing ideas to transform into action quickly. Therefore, although networks may require higher costs in policy formulation, there seem to be significantly lower costs in policy implementation.^[11] If not “lower” in the latter case, the costs might be necessary or even unavoidable.

Nevertheless, the effectiveness of networks still remains uncertain, even though such work as that of Provan and Milward^[12] provided important insights about network effectiveness, particularly in comparison with hierarchical arrangements in service implementation. The authors conducted a comparative study of mental health service networks in four U.S. cities to measure effectiveness of service implementation. The researchers pointed out that effectiveness of service implementation must be assessed at the network level for a direct reason: accomplishing a goal—client well-being—depends on a web of complex agencies, each providing multiple services to improve quality of care. Interestingly, they found that the most effective of the four mental health service networks is centralized around a core agency under direct external control within stable system environment.^[13] This finding runs counter to the conventional theory, which suggests that decentralized and highly flexible structural systems can operate more efficiently than traditional hierarchical arrangements. Further, Provan and Milward argued that Simon's^[14] loosely coupled “nearly decomposable” systems may not be efficient in environments such as mental health settings, where networks must be tightly linked to provide effective service to clients.

IMPLICATIONS AND RESEARCH AGENDA

For better or worse, public administrators have increasingly been confronted with network arrangements for program operations. Consequently, Jacksonian simplicity in administration is no longer appropriate, and it could even be disruptive in understanding the modern public policy configurations. Nevertheless, public administrators are not well prepared for new forms of governance, and few have treated networks seriously.^[1] This lack of attention implies limited practical lessons for

public managers who have increasingly been facing network arrangements, recognize them or not.

The emerging networks have significant implications for effective governance, in which the end results of public policies seem to rest on the understanding of complex patterns of interactions among policy actors. For instance, scholars in public management have noticed the emergence of the “hollow state” as one awkward result of establishing service delivery networks where government becomes only one of the many actors in the provision of public service, and perhaps even one with only distant oversight capacities as in the new arrangements about security checkers in airports. It is important that public managers recognize the dynamics of networked interactions, and also that they find ways in which program results are not only mutually beneficial to policy actors, but also meaningfully accountable to the large set of publics.

Some contend that the presence of policy networks implies a weakening of neutral and scientific public administration because of the emphasis on broad political interactions (e.g., Ref.^[7]). Policy networks certainly deny the politics–administration dichotomy and require “issue skilled” public managers who are well informed about the important issues among actors in the network settings.^[4] Specifically, the role of public manager in the network context is to reduce uncertainty underlying network arrangements and to induce cooperative solutions among the actors.

The final implication for present purposes is that conventional theory may not be suitable to network settings and permits little heuristic guidance in practice. Scholars have noticed that the unit of analysis has gradually shifted from the single agency to networked arrangements. Also, there are increasing needs for further scholarly research on networks to explore highly flexible structural arrangements, cause and consequences of networked interactions, and preferences and strategies of the various actors. Given the growing demands for theoretical agenda, game theory may be a practical alternative. In particular, Stoker^[8] offered some important heuristic lessons that can apply to networked interactions of actors who may cooperate but often reluctantly because of lack of knowledge of other actors' true preferences. He used game theory as a way of predicting “interdependent strategic alliance” among actors who have conflicting interests.

Basically, anomalies exist in the course of exploring networked interactions because the multiple values involved tend to be incompatible. Managing networks requires necessary transaction costs to induce cooperation, regardless of the strategies applied—whether coercion, persuasion, or rewards. In this sense, some scholars suggest that trust may be a critical element in inducing cooperation, and reducing transaction costs engendered by bargaining, contracts, and monitoring

(e.g., Ref.^[15]). However, empirical research does not support the connection between trust and cooperation in network settings. This empirical question and many others require continued attention.

New Institutional Economics

Brian E. Dollery

Joe L. Wallis

Department of Economics, University of Otago, Dunedin, New Zealand

INTRODUCTION

In common with the major earlier institutionalist tradition associated with Thorstein Veblen, Wesley Mitchell, John R. Commons, and Clarence Ayres, new institutional economics (NIE) represents a loose collection of ideas aimed at bringing institutional characteristics back to the core of economic analysis.^[1] Given its somewhat disparate nature, NIE is difficult to define with any degree of precision. Frant^[2] identified three “precursors” of NIE. First, Coase’s^[3] focus on the importance of transactions and the related problems of whether to employ markets or hierarchies to handle transactions, emphasized the costs attached to using the price mechanism. Second, there is the literature on the economics of property rights, deriving from Coase’s^[4] famous paper on how the assignation of property rights influences outcomes in the presence of externalities, which led to the so-called “Coase theorem.” And third, Alchian and Demsetz’s^[5] seminal attempt to apply the property rights paradigm to organizations engaged in productive activity, with the problems inherent in “team production,” like “shirking” and “monitoring,” is considered. Disagreement exists on the major dimensions of NIE. For instance, Rutherford^[1] adopts a fairly broad view of the main elements of NIE by including the economics of property rights,^[6] law and economics,^[7] rent-seeking and distributional coalitions,^[8] agency theory,^[9] transaction cost economics,^[10] game theory in institutional situations,^[11] and the new economic history of Douglas North.^[12] Matthews^[13] developed a fourfold taxonomy of NIE in which institutions are viewed as property rights, as kinds of contracts, as conventions, and as governance structures. By contrast, Boston et al.^[14] constrain their policy-orientated view of NIE to only two strands, namely, agency theory and transaction cost economics.

THE NIE CONCEPT

Unlike the older tradition, NIE scholars have few problems with a priori deductive theorizing. For example,

Furubotn and Richter^[15] have observed that:

The change in analytic approach adopted by the new institutionalists has not resulted from any deliberate attempt to set up a new and distinct type of doctrine in conflict with conventional theory. Rather, the tendency to introduce greater institutional detail into economic models has come about gradually over time because of the recognition that standard neoclassical analysis is overly abstract and incapable of dealing effectively with many current problems of interest to theorists and policymakers.

Although NIE does not contest the methodology of contemporary neoclassical economics, it makes several crucial changes to it. First, following Simon,^[16] NIE recognizes that in the real world, individuals possess an inherently limited capacity to process information and, accordingly, are “boundedly rational” in the sense that their calculations include only immediate and readily assimilated information. Bounded rationality necessarily implies that the complexities of actual economic exchange cannot be fully captured by hierarchical contracts or market mechanisms. This leads to a second difference between NIE and conventional economic analysis. Because bounded rationality prevents the construction of complete contracts between agents and principals, scope exists for opportunistic behavior by economic agents, who can conceal their preferences and actions from contractual partners.^[10] Indeed, it is precisely because of real-world phenomena, like bounded rationality and incomplete contracts, that economic activities have to be conducted in an environment characterized by asymmetric information and costly transactions, and it is these features that lend crucial importance to institutions.

Perhaps even more significant than these methodological issues are the differences between NIE and orthodox neoclassical analysis on the question of what should constitute the appropriate measure(s) to gauge economic efficiency. In common with the conventional approach, normative problems are usually framed in individualistic terms and focus on the efficiency of alternative conceivable institutional arrangements. But, many theorists working in the NIE tradition

have expressed strong reservations about using the allocative efficiency criterion to justify government intervention. For instance, Demsetz^[17] “nirvana fallacy” argument holds that by comparing real-world arrangements against the ideal of allocative efficiency rather than feasible institutional alternatives, policy makers have become far too inclined to prescribe government intervention. Similarly, De Alessi^[18] argued that many of the supposed inefficiencies identified in practical institutional situations by neoclassical economics are actually due to the existence of transaction costs.

Arguments along these lines have led many in the NIE tradition to favor a comparative institutions approach to the question of economic efficiency. The essence of this approach has been summarized by Furubotn and Richter,^[15] as follows:

Granting that the conventional efficiency standard is unsatisfactory, there is reason to seek a different criterion and move toward a concept of economic efficiency that takes fuller account of those real-life constraints that actually limit individual choices. This approach is precisely the one that many new institutionalist writers have adopted. These theorists point out that, in the real world, alternative systems of property rights exist and transaction costs are inevitably greater than zero. Hence, the “generalization” of neoclassical doctrine is advocated. The objective is, of course, to include in any general equilibrium model all of the constraints that decision makers must face in seeking to maximize utility.

The efficiency criterion required by this approach has been specified by De Alessi^[18] in the following terms:

Efficiency is being defined as constrained maximization. Efficiency conditions are seen as the properties of a determinate (equilibrium) solution implied by a given theoretical construct. On this view, a system’s solutions are always efficient if they meet the constraints that characterize it.

Often, notions of efficiency employed in the comparative institutions approach focus on productive or dynamic efficiency rather than on allocative efficiency. For example, North^[12] emphasizes the relative efficiency of institutions with reference to their impact on “social output” or “economic growth” and the ways in which they minimize transaction costs through time. This kind of argument does not indicate how “economic efficiency” defined in this way enhances individual utility or social welfare, and accordingly, is not completely satisfactory.

In general, it seems clear that theorists in the NIE tradition advocate a concept of efficiency that embodies organizational costs, like transaction costs, which

can be used to evaluate various feasible reorganizations of economic activity that could yield social gains net of the costs of reorganization. (See, for example, Refs.^[4,17,19,20].) This intellectual project is not without its critics^[21] and may be simply tautological. This argument has been summarized by Papandreou^[22] as follows:

The traditional notion of optimality in welfare economics has been criticized for comparing real-world outcomes with unattainable outcomes of a transaction-costless world. The alternative notion of “attainable” optimality implicit in models with endogenous transaction costs, suffers in that by offering a causal explanation of economic interaction it precludes other feasible alternatives with which to compare the outcome of the model. By disallowing comparisons of the “real-world” microeconomic model with microeconomic models that have different organizational costs, the set of feasible outcomes collapses to the outcome of the “real-world” model. Accordingly, the outcome that exists is the only possible one.

TRANSACTION COSTS

Despite the fact that Coase^[3] originally specified transaction costs as the “...cost of using the price mechanism” more than 60 years ago, a satisfactory definition of this concept remains problematic. As Allen^[23] has observed, “the literature on transactions costs is replete with papers which use the term and provide examples, but which never pause to define the phrase.”

In general terms, a transaction can be defined as an agreed exchange or transfer of goods and services across technologically separable boundaries. The costs involved in such an agreement and which facilitate such a transfer are collectively known as transaction costs.^[10] In other words, transaction costs are the costs of facilitating economic exchange or, in the language of Kenneth Arrow,^[24] the costs incurred in “running the economic system.” Transaction costs are contrasted with transformation costs (sometimes also called production costs), which are the costs involved in transforming inputs into outputs.

Theorists have adopted two generic ways of specifying transaction costs. First, it has been common to adopt somewhat narrow definitions of transaction costs closely bound with the notion of property rights. For example, Eggertsson^[25] delineated transaction costs as “the costs that arise when individuals exchange property rights to economic assets and enforce their exclusive rights.” Similarly, Barzel^[26] and McManus^[27] emphasized the costs of enforcement and negotiation of property rights. A second and more contemporary

view of the nature of transaction costs focuses on the costs of creating and maintaining the institutions characteristic of modern market economics. Furubotn and Richter^[15] described this approach as "...most easily understood as embracing all those costs that are connected with 1) the creation or change of an institution or organization, and 2) the use of the institution or organization." In the present context, we follow this latter approach.

The theory of transaction costs arose from Coase's^[3] question of why two institutions, the market and the firm, perform the same basic functions, yet continue to coexist. He argued that these two alternative methods of coordinating economic activities exist, because there are transaction costs associated with using the price mechanism. Accordingly, rational economic agents will seek to minimize transaction costs and will use markets or hierarchies, whichever is cheapest. Thus, for example, whether a firm decides to own or lease a particular machine will depend on the transaction costs involved.

The modern theory of transaction costs developed this line of thought and emphasizes the importance of the institutions underpinning exchange relationships, namely, markets, contracts, and firms in private sector settings. Transaction costs theory thus seeks to characterize the properties of transactions in order to determine which institution is optimal in any specific case. Williamson^[10] argued that the critical features of transactions are their uncertainty, the frequency with which they recur, and the extent to which parties to these transactions are obliged to make investments in transaction-specific assets. For example, once parties in an initial competitive market commit to a specialized transaction (involving, say, substantial investments in specific assets, or high "asset specificity"), then this leads an ongoing "small number" bargaining situation between the two parties, often termed bilateral bargaining. Williamson^[28] hypothesized that these kinds of arrangements encourage opportunistic behavior or "self-interest seeking with guile," and he called them "idiosyncratic" transactions, because the benefits of the transaction are dependent on the absence of opportunistic behavior in its execution. Obviously, specialized institutional arrangements will be required to govern idiosyncratic transactions.

Similarly, pervasive uncertainty, or the absence of perfect information, will also have a decisive effect on whether markets, contracts, or firms will be chosen to govern transactions. In general, Williamson^[10] argued that high levels of uncertainty will inhibit the use of long-term contracts in these cases. Analogous arguments also exist with respect to transactional frequency. For instance, in the absence of asset specificity, infrequent transactions will not usually require

contracts and will simply be undertaken through the market mechanism.

In common with other areas of NIE, transaction cost economics has been subjected to severe criticism. The first and most damaging line of attack is based on the proposition that it is not obvious that economic agents should wish to minimize total transaction costs rather than simply the transaction costs borne directly by themselves. Put differently, transaction costs minimization may take the form of a contest over "cost shifting" rather than a search for the optimal institutional arrangements. Second, although an attractive idea in principle, the desegregation of total costs into transformation costs and transaction costs may not always be feasible in practice.^[29] As Lane^[30] inquired: "could one measure the reduction in transaction costs by moving from a system of individual contracts to a hierarchy like a firm or bureau?" The transaction costs theory has also been criticized for the narrowness of its *homo economicus* behavioral assumption, which is asserted to disregard cultural, social, and other dimensions of human conduct.

For these and other reasons, transaction cost theory can at best offer only a partial explanation for real-world differences in economic organization. While it advances our understanding of the benefits and costs of alternative governance structures, it should, nevertheless, be applied with care and in tandem with other NIE models, like agency theory.

AGENCY THEORY

The literature on agency theory is centrally concerned with the ways in which one economic agent (the principal) can design and implement a contractual compensation system to motivate another economic agent (the agent) to act in the principal's pecuniary interests. Accordingly, agency theory is chiefly focused on the problem of economic incentives. By contrast, conventional neoclassical economics, with its reductionist construct of the organization as simply a production function converting inputs into outputs in the most productively efficient manner, assumed away principal-agent problems and the associated question of incentives. In the orthodox tradition, principals were perfectly informed on the nature of the tasks agents were hired to perform, and their subsequent actions could be monitored without cost. Agency theory can thus be viewed as the extension of the neoclassical theory of the firm to embrace "the problems posed by limited information and goal conflict within organizations."^[31] In other words, just as transaction costs theory adds realism to the theory of markets by including the costs attached to exchange relationships,

agency theory adds realism to the conventional “black box” conception of organizations.

A principal–agent relationship comes into being whenever a principal delegates authority to an agent whose behavior has an impact on the principal’s welfare. Numerous principal–agent relationships exist across virtually the entire spectrum of human endeavor. For example, principal–agent relationships include voters and their elected representatives, patients and physicians, employers and employees, shareholders and corporate managers, and so forth. The essence of all of these principal–agent relationships involves a trade-off for the principal. By delegating authority to an agent, the principal economizes on scarce resources by adopting an informed and able agent, but simultaneously takes on the risk that because the interests of the principal and agent will never be identical, the agent may fail to maximize the wealth of the principal. For instance, despite being paid a proportionate commission, real estate agents may wish to sell a property quickly at a lower price than could otherwise be obtained for the owner of the property. Because the interests of principals and agents are likely to diverge in most real-world relationships, agency theory focuses on the costs attached to such relationships and the efforts that principals and agents will take to economize on these costs. In their seminal contribution, Jensen and Meckling^[9] identified three categories of agency costs. First, monitoring costs arise from the resources principals invest in monitoring the behavior of agents and creating incentives for desirable behavior. Second, bonding costs will derive from resources invested by agents to guarantee successful outcomes to their principals. And third, residual loss costs consist of the losses to their well-being suffered by principals due to a divergence between their interests and those of their agents. According to Jensen and Meckling,^[9] total agency costs are thus comprised of the aggregate of monitoring costs, bonding costs, and residual loss costs.

The extent of total agency costs is postulated as dependent on the characteristics of particular principal–agent relationships. For example, in a typical agency relationship, agents almost always possess more information about the task assigned and the relative efficacy of their own performance. Agents often take advantage of this asymmetry of information by engaging in shirking or opportunistic behavior inimical to the interests of principals, and clearly, the greater the extent of this behavior, the higher will be the level of total agency costs.

Although in its initial stages, agency theory was applied exclusively to the firm, and especially, the modern corporation with its characteristic separation of ownership from control quintessentially representative of a principal–agent relationship, it was soon used

more widely once its explanatory powers were recognized. Jensen and Meckling^[9] recognized the generality of agency theory:

The problem of inducing an “agent” to behave as if he [or she] were maximizing the “principal’s” welfare is quite general. It exists in all organizations and in all co-operative efforts—at every level of management in firms, in universities, in mutual companies, in co-operatives, in governmental authorities and bureaus, in unions, and in relationships normally classified as agency relationships such as are common in the performing arts and the market for real estate.

Two specific aspects of the agency problem have received widespread attention in the literature. First, the phenomenon of adverse selection occurs due to informational asymmetries in principal–agent relationships. For example, because unhealthy people are more inclined to purchase health insurance, they will be overrepresented in the pool of insured people. In turn, this will force the price of insurance to rise, inducing many low-risk healthy individuals to forego health insurance. Second, the problem of moral hazard arises when a party to a contractual relationship can affect the outcome of this arrangement to their own advantage. For instance, if a person is fully insured and cannot be accurately monitored by an insurance company, then their behavior may change after the insurance has been purchased to induce larger payments. Adverse selection occurs due to information asymmetries in principal–agent relationships. For example, older people typically experience more difficulties in obtaining health insurance.

Given the problems inherent in principal–agent relationships, like adverse selection and moral hazard, a good deal of agency theory has focused on resolving these problems by specifying the optimal form of contracting (Refs.^[32,33]). Substantial progress has been made in a variety of economic relationships, including labor, land, credit, and product markets, and, more recently, in the public sector.

Agency theory is not without its critics (see, for instance, Ref.^[34]). In common with other areas of NIE, including transaction costs economics, agency theory has been criticized for the restrictive and descriptively unrealistic nature of its *homo economicus* behavioral postulate, which is postulated as neglecting the complexities of human relationships. More specifically, agency theory has been attacked for overlooking issues of authority and power in principal–agent relationships, and in particular, for emphasizing the role of opportunistic behavior by agents, while ignoring opportunism by principals. It has also been argued that agency theory places a heavy reliance on single principal–agent models that ignore questions of

competing principals or of uncertainty surrounding the identity of principals. Moreover, it has been observed that the policy implications that flow from agency theory are unclear, especially in public sector contexts.

New Public Management

Eran Vigoda

School of Political Sciences, University of Haifa, Haifa, Israel

INTRODUCTION

New Public Management represents “*an approach in public administration that employs knowledge and experiences acquired in business management and other disciplines to improve efficiency, effectiveness, and general performance of public services in modern bureaucracies.*” Despite contradictory views about the meaning and implications of this doctrine, there is no doubt that it has become extremely influential in public administration theory and practice since the 1980s.

In the last decade, we have witnessed an ongoing debate between scholars and practitioners of public administration on the best way to revitalize and renew old style bureaucracies. Since the early 1980s, much work has been conducted in public administration theory and practice that claimed to go beyond the conservative approach in the field. Modern public administration has been urged to innovate and reform itself in a style better suited to the twenty-first century and the growing demands for higher efficiency and effectiveness. Drawing on the experience of the business/industrialized/private sector, scholars have suggested taking a more “demanding” attitude toward the dynamics, activity, and productivity of public organizations. Similarly, a significant conceptual change has transformed the “old” style of public administration into the “new” approach of public management. This “liberalization” of public administration is recognized today as the New Public Management (NPM) doctrine.

What is the meaning of NPM? What are its roots, and in what way is it actually a *new* arena in the study of the public sector? Has it achieved enough success in recent years to justify further inquiry into its principles and promises? These questions, as well as many others, have received considerable attention during recent years and, in fact, a large number of varying opinions have emerged. Proponents of this approach have provided detailed explanations and a variety of examples that demonstrate the enormous positive impact of the approach. Those who critique NPM counter with the argument that it has nothing new or notable to contribute to the field. They, thus, tend to treat it as a seasonal fashion that will eventually fade in face of other “new” doctrines. Therefore, advocates of NPM continuously face critics who are unconvinced

as to the merits of NPM as an administrative philosophy.

THEORETICAL FOUNDATIONS

To better resolve these conceptual and practical conflicts regarding the contribution of NPM to public administration, one must become familiar with several fundamental concepts. The first and probably the most basic premise of NPM emerges from the distinction between two proximate terms or fields of research—*administration* and *management*. Since the late 1880s, the monopoly on the term “administration” has been in the hands of political scientists. Scholars like Goodnow and Wilson perceived public administration as a separate and unique discipline that should consist of independent theory, practical skills, and methods. Yet, the term “management” referred to a more general arena, used by all social scientists and mainly by those who practice and advance theories in organizational psychology and business studies. Consequently, conservative administration science tends to analyze the operation of large bureaucratic systems, as well as other governmental processes aimed at policy implementation. Management, on the other hand, refers to the general practice of empowering people and groups in various social environments and the handling of manifold organizational resources to maximize efficiency and effectiveness in the process of producing goods or services.

A second premise of NPM derives from the nature and values of democratic nations. Citizens of modern democracies act as voters and delegate power to politicians and administrators to do what is best for people and societies. However, representative democracy leaves its fingerprints on the actions and operation of bureaucracies. For many years, bureaucracies worked in a manner far removed from citizens and with a lack of sensitivity to the growing needs and demands of heterogeneous populations. As suggested by Rainey,^[1] the 1960s and the 1970s were characterized by the initiation of unsuccessful public policies in Europe and in America. At least some of these unsuccessful experiences were due to lack of reliable analyses of the needs and demands of the public, while other failures were caused by incorrect assessments regarding

the power of bureaucracies. Over the years, efforts by governments to create extensive changes in education, welfare systems, health programs, internal security, and crime control were widely criticized for being ineffective and unproductive and for misusing public funds. Responsiveness to the real needs and demands of citizens was paltry. The crisis in practical public policy implementation, together with the increased cynicism of citizens toward government and public administration systems, generated rich scholarly activity aimed at creating useful alternatives for improved policy in various social fields, as well as in the administrative processes in general. Voters expressed their dissatisfaction with elected officials and, hand in hand with the academic community, called for extensive reforms in government. This call produced a large number of working papers, articles, and books that proposed extensive administrative changes. One of the most inspiring works, Osborne and Gaebler's *Reinventing Government*,^[2] is frequently mentioned as the unofficial starting point of such reforms, later known as NPM.

As time went on, a growing number of political scientists perceived public administration as an *old* and declining discipline. It was unable to provide the public with adequate practical answers to its demands and moreover, left the theoreticians with epidemic social dilemmas awaiting study. Evidence for this shift in attitude appears in the transformation of many schools of public administration into schools of public management that took place during the 1980s and 1990s. Looking for alternative ideas, management theory was proposed as a source for a new and refreshing perspective. It was suggested that public management instead of public administration could contribute to a new understanding of how to run the government more efficiently and thereby overcome some of its pandemic problems.

CORE DEFINITIONS

Based on the growing alienation of citizens, the ineffective performance of bureaucracy, and the growing demands for a real change in public policy and activity, NPM flourished. But what is the essence of NPM and the best way to define it? During the last two decades, many definitions have been suggested. In the early 1980s, Garson and Overman^[3] defined it as *an interdisciplinary study of the generic aspects of administration... a blend of the planning, organizing, and controlling functions of management with the management of human, financial, physical, information and political resources*.

Hood^[4] identified seven doctrinal components of NPM: 1) "hands on" professional management in the

public sector; 2) explicit standards and measures of performance, which were later defined as PIs (Performance Indicators); 3) greater emphasis on output control; 4) a shift to the disaggregation of unit; 5) a shift to greater competition; 6) a stress on private sector styles of management practice; and 7) a stress on greater discipline and parsimony in resource use. This definition implies that NPM relies heavily on the theory of the marketplace and on a business-like culture in public organizations. Other definitions were suggested in the 1990s and drew on the extensive writing in the field. For example, Hays and Kearney^[5] found that most of the studies on NPM had mentioned five core principles of NPM and thus concluded that they represent the most important philosophy of the discipline: 1) downsizing—reducing the size and scope of government; 2) managerialism—using business protocols in government; 3) decentralization—moving decision making closer to the service recipients; 4) debureaucratization—restructuring government to emphasize results rather than processes; and 5) privatization—directing the allocation of governmental goods and services to outside firms.^[6] All of these principles are mutually related, relying heavily on the theory of the private sector and on business philosophy but aimed at minimizing the size and scope of governmental activities. Integrated with ideas rooted in political economy, they have now been applied to public sector institutions.

Hence, governments that are far from being simple businesses have been encouraged to manage and run themselves like businesses. An integrative definition for NPM that relies on the previous works would thus argue that NPM represents "an approach in public administration that employs knowledge and experiences acquired in business management and other disciplines to improve efficiency, effectiveness, and general performance of public services in modern bureaucracies."

WHAT MAKES PUBLIC MANAGEMENT NEW?

New Public Management is growing in popularity in North America and across the world, and many governments have adopted ideas and recommendations that have proven beneficial, thereby arguing for the continued implementation of this strategy. A consensus exists today that NPM has become extremely popular in theory and in practice in public arenas. Relying on an extensive survey of public management research in America, Garson and Overman^[3] argue that this increasing popularity was due to the more aggressive connotation of the term "management" in comparison with "administration."

Yet, is NPM really a new doctrine in public administration or just another variation on old concepts and ideas? There is no doubt that the increased impact of new ideas and methods from the field of public management into that of administrative science is essential and natural. It reflects a special focus of modern public administration that must not be ignored. It may also be viewed as a major segment of the broader field of public administration since it focuses on the profession and on public managers as practitioners of that profession. Thus, public management had indeed some new elements of vital and innovative thinking. Furthermore, it emphasizes well-accepted managerial tools, techniques, knowledge, and skills that can be used to turn ideas and policy into successful programs of action.

Other scholars delineate (e.g., Ref.^[7]) six differences between public administration and public management that turn the latter into a new field of study and practice: 1) the inclusion of general management functions such as planning, organizing, control, and evaluation in lieu of simple discussion about social values and the conflicts of bureaucracy and democracy; 2) an instrumental orientation favoring the use of the criteria of economy and efficiency in lieu of equity, responsiveness, or political salience; 3) a pragmatic focus on mid-level managers in lieu of the perspective of political or policy elites; 4) a tendency to consider management as generic, aimed at minimizing the differences between the public and private sectors in lieu of accentuating them; 5) a singular focus on the organization where external relations are treated in the same rational manner as internal operations in lieu of a focus on laws, institutions, and political bureaucratic processes; and 6) a strong philosophical link with the scientific management tradition in lieu of close ties to political science or sociology.

While the emergence of NPM is frequently related to the increasing impact of positivist behavioral science on the study of politics and government (e.g., Ref.^[7]), the practical aspect of this process should also be considered. Practical public managers, as well as political scientists, refer to the difficulties in policy making and policy implementation that faced many Western societies in Europe, America, and elsewhere during the 1970s. These practical difficulties are viewed today as an important trigger for the development of NPM. Reviewing two recent books on NPM,^[8,9] Khademanian^[10] argues that American and Westminster advocates of the field find common ground in explaining why such reforms were necessary. The problem of an inflexible bureaucracy that often could not respond efficiently and promptly to the public needs contradicted basic democratic principles and values in these countries. Elegantly, Peter Aucoin summarizes a “trinity” of broadly based challenges with which Western

democracies have coped and with which they will probably continue to struggle in the future, partly through management reform: 1) growing demands for restraint in public sector spending; 2) increasing cynicism regarding government bureaucracies’ responsiveness to citizen concerns and political authority and dissatisfaction with program effectiveness; and 3) a growing international, market-driven economy that does not defer to domestic policy efforts. It seems that these challenges have led many Western governments in America, Britain, New Zealand, Canada, and elsewhere to the recognition that firm reforms and changes in public service should be made.

CRITIQUE OF NPM

Certainly, the NPM approach suggests a different type of interaction between citizens and rulers in democracies. However, the roots of such interactions can be found a century ago. For example, Weikert^[6] asserted that “the ideas behind NPM are not new” and that “NPM builds on a long history of using business practices in government and reflects a resurgence of old ideas about the form and functions of government.” During the first years of the twentieth century, reformers and business leaders demanded greater accountability in local government, and many politicians, as well as public officials, turned to business principles to improve governmental activities, invigorate performance, and reduce corruption. However, the vision of NPM is also far different from the old business-guided governance in that it looks to decrease government size and minimize its involvement in citizens’ lives. As is evident from the above principles, NPM advocates that governments and public administrative bodies view citizens as clients/customers of the public sector, while governments and the public sector are perceived as managers of large bureaucracies. According to this outlook,^[3,8,11] the state and its bureaucratic subsystems are equivalent to a large private organization operating in an economic environment of supply and demand. In this spirit, a major goal of government is to satisfy the needs or demands of citizens, namely to show higher responsiveness to the public as clients. In line with this, it is obvious that modern states must rely more on private and third-sector institutions and less on government to satisfy the societal needs of heterogeneous populations. The goal of satisfying the needs of citizens became central to the NPM philosophy.

Nevertheless, NPM may be criticized for not doing enough to encourage and incorporate the idea of collaboration or partnership between citizens and the public sector and for failing to apply these themes to modern managerial thinking.^[12] Unlike traditional public administration, the NPM movement focuses

on citizens as sophisticated clients in complex environments. The principles of NPM are compatible with theories of political economy such as regulative policy by governments or the policy of transferring responsibilities from the state sector to the private and third sectors. These ideas, and the governmental policies deriving from them, frequently challenge various social democratic principles, norms, and values in Britain, America, and many other Western democracies. Public authorities were urged to treat the public well, not only because of their presumed administrative responsibility for quality in action but also because of their obligation to marketplace rules and to economic demands and above all because of their fear of losing clients in an increasingly competitive businesslike arena. In fact, while NPM is an improvement over more classic views of public administration that saw citizens as subjects or voters, it does not go far enough in fostering the idea of vital collaboration between citizens, governments, and the public sector, which is in the essence of democratic civil society.^[13]

In line with this, “neo-managerialism”^[14] notes an additional obstacle to productive partnership that must also be recognized and surmounted. According to Terry, neo-managerialism supports the idea that administrative leaders should assume the role of public entrepreneurs. However, “public entrepreneurs of the neo-managerialist persuasion are oblivious to other values highly prized in the U.S. constitutional democracy. Values such as fairness, justice, representation, or participation are not on the radar screen (and) this is indeed, troublesome.” In many respects neo/new managerialism and NPM encourage passivity among the citizenry. They impart to citizens the power of *exit* (which indeed was virtually unavailable in the past), but at the same time, they discourage use of the original power of *voice* by citizens who may have much to contribute to their communities.^[12] Exit is an economic choice, while voice is more of a political selection by individuals in and around organizational systems. Exit is also classified as a generally destructive behavior, while voice is a productive one. According to this argument, NPM restricts and discourages the productive political voices of the people.

Hence, recent developments in the study of NPM have focused on the responsibilities of governments and public agencies in their interaction with citizens but similarly have paid far less attention to the active roles of citizens and to their obligations to the community. Most of the up-to-date NPM literature favors massive socialization of business management practices in the public sector to provide governments with better tools for policy implementation. But on the other hand, these orientations and practices have not yet been integrated with another core-construct of healthy democracies—genuine collaboration and

partnership with citizens based on equal opportunities for participation and massive involvement in running public life more effectively. This lack of emphasis on the idea of partnership and collaboration, in favor of good responsive management, may be deemed a flaw in contemporary NPM theory.

CONCLUSION: THE ONGOING PURSUIT OF “NEW” AND “NEWER” INITIATIVES IN PUBLIC ADMINISTRATION

Scholars agree today that at least some of the accumulated wisdom of the private sector in developed countries is transferable to the public sector. In an attempt to “liberate” the public sector from its old conservative image and moribund practice, NPM was advanced as a relevant and promising alternative. Thus, NPM literature has tried to recognize and define new criteria that may help in determining the extent to which public agencies succeed in meeting the growing needs of the public. New Public Management has continuously advocated the implementation of specific performance indicators used in private organizations to create a performance-based culture with matching compensatory strategies. It has recommended that these indicators be applied in the public sector since they can function as milestones by which to better gauge the efficiency and effectiveness of public agencies.

Moreover, citizens’ awareness of the performance of public services was suggested as a core element of NPM since it can increase the political pressure placed on elected and appointed public servants, thereby enhancing both managerial and financial efficiency in the public sector. Scholars who advocate NPM compare this process of public accountability to stakeholders/citizens to the role adopted by financial reporting in the private/corporate sector. As in the private sector, increasing external outcomes can have meaningful impact on internal control mechanisms, as managers and public servants become more sensitive to their duties and more committed to serving citizens as customers.

In view of the above and looking toward the future, Lynn^[15] suggested that NPM of the late 1990s has three constructive legacies for the field of public administration and for democratic theory and practice: 1) a stronger emphasis on performance-motivated administration and an inclusion in the administrative canon of performance-oriented institutional arrangements, structural forms, and managerial doctrines fitted to a particular context—in other words, advances in the state of the public management art; 2) an international dialog on and a stronger comparative dimension to the study of state design and administrative reform; and 3) the integrated use of economic, sociological, social-psychological, and other advanced conceptual models and heuristics

in the study of public institutions and management, with the potential to strengthen the field's scholarship and the possibilities for theory-grounded practice.

It seems that the ongoing debate about the net contribution and added value of NPM to the study and practice of public administration will continue. Whether it is a "new" approach, a partly new doctrine, or an old lady with a new hat, it is obvious that NPM is responsible for some of the meaningful transformations witnessed by modern societies in the last few decades. It is also likely the "newer" doctrines and methods will evolve along with bureaucratic, political, technological, and cultural developments. New Public Management has made its mark, but this is only one link in an endless chain of scientific advancement.

New Public Service

Wouter Vandenabeele

Public Management Institute, Catholic University Leuven, Leuven, Belgium

Annie Hondeghem

Katholieke Universiteit Leuven, Leuven, Belgium

INTRODUCTION

The concept “new public service” has multiple meanings in the field of public administration. Patricia Ingraham and David Rosenbloom^[1] use it when referring to the new public administration movement. Paul Light^[2] uses the expression in a more empirical manner when describing the characteristics of a new generation of public servants at the beginning of the 21st century. However, none of those have received as much resounding responses in the international public administration community as the movement built on work in democratic citizenship, community and civil society, and organizational humanism and discourse theory. The remainder of this entry deals with this last, and by far most influential, meaning of new public service developed by Robert and Janet Denhardt.^[3] Conceived to counterbalance earlier movements in public administration, new public service in its initial description is contrasted to both “classical” public administration (hereafter classical PA) and New Public Management. Next to this description, its implication on administrative ethics is assessed. Finally, evidence of such a new public service ethic is discussed.

COUNTERBALANCING NEW PUBLIC MANAGEMENT

The classic approach to public administration has increasingly come under attack. The politically neutral and hierarchical bureaucracy associated with Woodrow Wilson^[4] and Max Weber,^[5] although it should get fair credits for its achievements, is often solely associated with bureaucratism and inefficiency. New Public Management tried to remedy these critiques not only by introducing private sector techniques into public administration, but also by adopting private sector values of cost effectiveness and entrepreneurial spirit as a normative framework. Against these new entrepreneurial principles, classical PA with its

negative image was bound to be judged bleakly. However, New Public Management was not entirely uncontested either, as numerous authors have criticized it.^[6] The Denhardts tried to bundle these critiques and use them as a starting point for an alternative normative framework to lay against the deficiencies of New Public Management principles: new public service. They define new public service as “a set of ideas about the role of public administration in the governance system that places public service, democratic governance and civic engagement at the center.”^[7]

SEVEN PRINCIPLES OF NEW PUBLIC SERVICE

By stating new public service in terms of normative principles, the Denhardts hope to achieve a more fair comparison of the traditional public administration values with New Public Management, a comparison they felt was not granted to classical PA. They state seven principles and contrast each of them with both classical PA and New Public Management.

1. *Serve, rather than steer.* Classical PA’s duty was to “row” society. Top-down leadership should provide the necessary services for society to survive. In New Public Management, leadership had to “steer” society. This meant setting policies, leaving implementation to agents (governmental or nongovernmental) and evaluate afterwards. Leadership was about creating incentives for agents to implement policies. Leadership in new public service is based on values and it is shared throughout the organization and with the community. Leaders must share power and lead with passion, commitment, and integrity, thus empowering citizenship.
2. *Seek the public interest.* In classical PA, no administrative responsibility to protect the public interest was necessary, as the public interest was determined by elected officials. In New Public Management, the public interest was

realized by the invisible hand of the free market, as it was conceived as the aggregation of individual or self-interest. New public service wants administrators to actively create a shared notion of public interest, consistent with democratic norms.

3. *Think strategically, act democratically.* The implementation of policies should not occur in a top-down manner, as in classical PA, or in a private or a utilitarian coproduction between individuals and government, as in New Public Management. Rather, the whole process should be a collective effort (for example, a network) with the community. It should be an interaction to create a lasting responsiveness of the government towards the community.
4. *Serve citizens, not customers.* In classical PA, people are considered clients or subjects. Therefore, little attention was given to the quality of the services rendered by government. New Public Management changed this drastically. According to public choice theory, people became customers. The quality of services delivered to these customers was consequently the most important aspect of governmental action. Although new public service recognizes the importance of quality of services, people are not mere customers. As citizens they have multiple roles, and they should express this in developing a concern for their community. Government should enable and support them in this community building, not just control or provide customer services.
5. *Value citizenship and public service above entrepreneurship.* The policy-role of the administrator in classical PA is kept deliberately limited. Whenever he or she enters this process, various “cloaks” or reasons are mentioned (for example, expertise or discretion) to cover the value-laden influence on the process. New Public Management expects administrators to act as entrepreneurs. Public servants are urged to develop policies and handle public funding as if it was their own money to achieve their targets. New public service thinks of administrators as “stewards” of public resources, rather than owners. They thus have a larger responsibility to their community. By assuming the role of “professional” citizen, public servants must maintain democratic values in administration and see to the responsiveness of government towards the community.
6. *Value people, not just productivity.* In classical PA, an organization was based on hierarchy and control, as this was the only way to make

people achieve the desired results. New Public Management based itself on public choice and principal agent theory to declare economic self-interest as the sole source of motivation. Therefore, incentives to satisfy this self-interest were used to motivate people. According to new public service, both approaches present only a very narrow view. Organizations are more likely to persist and deliver results if they operate through processes of collaboration and respect for people. The shared values of an organizational culture are very important in this respect.

7. *Accountability is not simple.* In classical PA, accountability was mainly hierarchical. This accountability scheme was grounded on the view of a monolithic bureaucracy, lead by a politically accountable government. New Public Management made entrepreneurial administrators accountable to values of efficiency and cost effectiveness, as it thought of the market as the main governance structure. According to new public service, the governance structure is much more complex. Public administrators are called upon to be responsive to various institutions and values within this structure. It is the role of public servants to explain and disseminate these governance complexities to the public and broker the different interests.

FOUNDATIONS OF NEW PUBLIC SERVICE

The Denhardtts ground the new public service framework on different foundations. The origins of the framework are certainly not new, as some of these date back to earlier movements in the science of public administration (e.g., new public administration), or even go back to the cradle of western democracies. Combining these different foundations into a set of norms provides an enormous intellectual heritage to structure governance.

At the foundation are theories of democratic citizenship. This citizenship is not defined from a legal point of view but as the individual's capacity to influence the political system. It is not only based on self-interest because an important element is public spirit, which enables people to look beyond their parochial self-interest. This public spirit can be nourished by participation, deliberation, and promotion of justice. The presence of a public spirit enables citizens to run government (that is what public administration is all about) in a democratic manner. Only then is government responsive to the people as citizens and not as mere clients, customers, or subjects.

A second element on which new public service is grounded are communities and civil society. Western (and especially American) democracy is based on a tradition of citizens engaged in all sorts of associations. This tradition should be reflected in public administration for two interconnected reasons. Public administration can build further on the available stock of social capital building even stronger networks in order to solve public problems. And it should also enable public administration to help to create and support communities and reinforce social capital.

Third, new public service is based on organizational humanism. Following the critique of hierarchy, control and positivism in classical PA, new approaches to management were adopted. According to organizational humanism, organizations should enhance human development rather than inhibiting it by hierarchy and control. The Denhardtts substantiate this by referring to the new public administration movement, which tried to offer a value-based alternative for classical PA.

Finally, new public service substantiates itself on postmodern discourse theory. This is a critique on separating the reality of organization from values, as propagated by the positivist approach to administration. According to postmodernism, this separation prevents a full understanding of the meaning of realities in public administration. This understanding can only be achieved through open communication. As public problems will be more easily solved through discourse and dialogue, government should be exemplary of open communication.

THE ETHICS OF NEW PUBLIC SERVICE

As a normative framework for a governance structure, new public service is inevitably linked with ethics. Moreover, these ethics are an important feature within the framework, as it explicitly refers to ethical behavior of administrators as a factor for success. The comparison of the new public service ethics with its predecessors, linked with classical PA and New Public Management, unveils some striking differences.

In classical PA, the prevailing system of ethics is the ethic of authoritative command. According to academic moral philosophy, the ethics of authoritative command are a consequentialist system.^[8] It has a certain definition of the good as a foundational principle and a theory of obligation by which an act is moral if it leads to the realization of that good. This good has to be politically determined outside the administration. The role of bureaucrats is limited to obedience to the representatives and the rules they make, following the tradition of the policy-administration dichotomy.

The ethics of New Public Management, although its manifestation could not be more different from classical PA, go along similar consequentialist lines. But instead of focusing on legal accountability of the administrators, attention is shifted towards a good that is determined by market forces instead of democratic procedures.^[9]

A major problem with the ethic of authoritative command is its lack of fit with reality. Governance has become such a complex matter that administrators cannot just follow rules anymore, they are bound to exercise some level of discretion. Therefore, the ethics of authoritative command refer to a situation that is to some extent fictional.

The ethics of New Public Management pose an even bigger problem. As it turns to market forces for determining the good, it threatens the very foundation of any democratic governance structure.^[10]

The ethics of new public service deviate from this approach when referring to organizational humanism, communitarianism, citizenship, and discourse theory.

Communitarianism reaches back to Aristotle's notion of man as a social/political animal and therefore man gets his identity from his community. Communities cultivate certain virtues to benefit the community and which man has the duty to realize. These virtues are at the center of communitarian ethics, but their interpretation is closely connected with the nature of a specific community.

The ethics of democratic citizenship lean very close to communitarianism. Citizens have to look beyond self-interest to a larger public interest of the community they belong to and whose fate is at stake. In fact, some consider the ethics of citizenship as an element of the ethics of communitarianism as it leads to citizens defining themselves in terms of their community.^[8]

Discourse theory states that not only man is a social construction. Reality as a whole finds its origins in social interaction. Only conversation can provide a clear understanding of reality and produce healthy individuals. "Keeping the conversation going" is therefore the ethical thing to do. As communities are obviously an important source of interactions, this also leans very close to communitarianism.

Although the ethics of new public service solves some problems, classical PA and New Public Management were struggling with, it has problems of its own. The reliance on benign communities from which virtues can be derived is an important weakness of the system. A community's shared heritage can be oriented towards oppression or destruction. After all, there is no empirical evidence that communities are intrinsically benign. Ancient Sparta, for example, was oriented towards war and oppression of the surrounding communities and this was reflected in the virtues it advocated. Also, communitarian tradition is less

outspoken in continental Europe. Historically, the religious pillars and the welfare state overcame the needs for other associations. With the decline of religious pillarization, it remains a question whether there is sufficient breeding ground to substantiate a system of communitarian ethics. Next to this, communitarianism carries the seed of totalitarianism. Enveloping every aspect of life in a community, excess application leaves no room for eccentric or creative behavior anywhere in society. At best, this can be unbearably boring. Worse would be that public administration reaches totalitarian dimensions and that it advocates a policy of elimination of all nonconformist individuals, like in George Orwell's "1984." Another critique is that some consider discourse theory ethics not viable in an era dominated by mass communication. Preponderance of this one-way method of communication prevents a discourse to fully develop. Finally, a general problem of new public service ethics is the lurking danger of relativism, because it does not have an overarching ethical principle. With moral values that are relative to community or discourse, anything can be considered ethical (or nonethical). In such an excessive application, discourse theory ethics therefore offers little guidance to public administration practitioners.^[11]

EVIDENCE OF NEW PUBLIC SERVICE ETHICS

As in seemingly every system of administrative ethics, new public service ethics has its inherent problems. These inherent problems can only be overcome by a belief in the rightness of the system. To avoid fundamentalism, however, research results can moderate excess application of an ethic. Put the other way around, these results can demonstrate the relevance of such ethics in particular fields of public administration.

In the case of a new public service ethics, a lot of value-based public administration research has been reported. Much of it is based on the public service motivation concept by Perry.^[12] This is a kind of value-based motivation, covering four dimensions: attraction to public policy making, compassion, commitment to the public interest and civic duty, and self-sacrifice. Behavior stemming from this motivation is an empirical expression of new public service ethical values. Brewer and Coleman^[13] link public service motivation to whistle blowing, resulting in high performance and high levels of job commitment. Naff and Crum^[14] find that public service motivated public servants are more satisfied and have higher performance ratings. Therefore, Rainey and Steinbauer^[15] suggest that public service motivation is critical in delivering public services. But also outside the narrow field of public administration, new public service ethics is visible. Brewer^[16] finds that because of their public

service motivation, public servants are more likely to contribute to social capital than others are.

CONCLUSIONS

The Denhardtts conceive new public service as an alternative normative framework on which to ground public administration and contrast it with both classical PA and New Public Management. The new public service rests on an eclectic set of foundations of democratic citizenship, communitarianism, and postmodern discourse theory, which has its implication in the ethical sphere. Although new public service ethics is able to solve some ethical problems of both classical PA and New Public Management, it has its inherent problems that limit its applicability. However, this need not to be insurmountable, as abundant empirical evidence of behavior in line with new public service ethics demonstrates. Whenever applied wisely and prudently, new public service and its associated ethical framework can be a valuable element in public administration.

New Sciences Approach and Public Administration

Göktuğ Morçöl

School of Public Affairs, Pennsylvania State University at Harrisburg,
Middletown, Pennsylvania, U.S.A.

INTRODUCTION

“New Sciences” is a term used to refer to a group of natural science theories that have implications for the social sciences in general, and public policy and administration in particular. The philosophy and methods of the new sciences are evolving, and there is no definitive list of theories that are commonly considered as the new sciences, but *quantum mechanics*, *chaos and complexity theories*, *autopoiesis theory*, and *fuzzy logic* are the ones from which implications have been drawn for the social sciences. These are the theories that will be discussed in this article.

New science theories challenge the deterministic and objectivist assumptions of the classical (Newtonian) science, which is the primary source of the explicit and implicit ontological and epistemological assumptions of many natural and social scientific theories. Newtonian scientific thinking, which has been predominant since the seventeenth century, is based on the view that physical reality is fully determined and can be understood objectively and in terms of mechanistic principles (i.e., by reducing it into its parts and analyzing the relations between them). Newtonian thinking has been influential in the social sciences. For example, some theorists point out that our organizations are designed from Newtonian images of the universe: We assume that our methods can help us perceive the world objectively, separate organizations into parts for management purposes, attempt to influence individual behaviors by exerting direct force on them, and make plans to ensure predictability.^[1] Also, arguably, the policy analytic images of mechanical and linear relationships between policy inputs and their outcomes are Newtonian. Presumed mechanical and linear relationships between phenomena create a predilection for using quantitative methods in social inquiry. Some social scientists equate the use of quantitative methods with scientificity and assume that quantitative forms of knowledge are inherently superior to qualitative forms of knowledge. New science theories question and challenge these deterministic, objectivist, linear, and quantificationist assumptions and offer epistemological and methodological alternatives.

QUANTUM MECHANICS

Quantum mechanics is about subatomic phenomena, but it has broader ontological and epistemological implications. There are different, and sometimes conflicting, interpretations of quantum phenomena, but the term quantum mechanics is most often used to refer to the Copenhagen interpretation, whose main principles were formulated by Niels Bohr, Werner Heisenberg, and others in the early twentieth century.

The central insight of the Copenhagen interpretation is that all forms of radiation and all subatomic “particles” have, in fact, complementary characteristics: They are both wave and particles. This is called the *complementarity principle*. The *uncertainty principle*, which states that the position and momentum of a particle cannot be measured accurately at the same time, is a special case of the complementarity principle. (Position is a particle property, and momentum is a wave property; the more we know about the wave aspect of subatomic reality, the less we know about its particle aspect.) The complementarity and uncertainty principles contradict the Newtonian ontological assumption that the ultimate units of matter (particles) exist as discrete objects and in precisely definable locations in space and move around in precisely predictable trajectories.

The complementarity and uncertainty principles led to the ontological interpretation that reality—at least, at the subatomic level—is a probability function and to a questioning of the presumed distinction between the knowing subject and the object of his/her knowledge. Quantum scientists have shown repeatedly that subatomic phenomena “behave” as wave, when experiments are set up to detect waves, and as particles when experiments are set up to detect particles. Thus, it is concluded, methods of inquiry interfere with reality; in other words, we participate in reality as we observe it.

E. Samuel Overman derived conclusions from quantum mechanics for public policy and administration.^[2,3] His key insight is that quantum mechanics heralds a convergence between the natural and social sciences: It has shown that natural phenomena are indeterministic and unpredictable at the most

fundamental level of existence, very much like social phenomena as described by many social scientists. According to Overman, the complementarity principle of quantum mechanics suggests that the classical dichotomies of public administration and policy analysis—politics versus administration, facts versus values, theory X versus theory Y, rationality versus disjointed incrementalism, centralization versus decentralization—are in fact complementary aspects of phenomena. Conceptual dichotomies are epistemological illusions.

He suggests that Simon's concept of "bounded rationality" and the Hawthorne effect are examples of the uncertainty principle. Social reality cannot be observed in its entirety or unobtrusively. A social observation involves a complex relationship between the observer and the observed. According to Overman, quantum mechanics suggests a constructivist epistemology, that understanding of phenomena is a matter of interpretive construction. In public policy making, realities are constructed and constituted through symbol manipulation and image making. Performance appraisals in organizations are another example of participating in reality while measuring it. Although the appraisals are aimed at providing "objective" measures of employees performances, they end up influencing performances.

CHAOS AND COMPLEXITY THEORIES

What emerged as *chaos theory* in the late 1970s morphed into the *sciences of complexity*—alternatively called *complexity theory* or *complex systems theory*—in the 1990s. The sciences of complexity are composed of a constellation of theories that question the deterministic ontological assumptions of Newtonian physics. Some complexity theorists also offer interpretivist and phenomenological epistemological perspectives for science.

Complexity is customarily defined in terms of the number of elements in a system. Complexity theory expands this definition and says that it involves not only the number of elements, but also the non-linear (disproportionate) nature of relationships between them—as opposed to linear (proportionate) relationships. As such, complexity creates the conditions for unpredictability in the future behavior of a system. Complexity theorists also adopted the system-theoretic notions that the properties of complex systems emerge endogenously, and that once they do, they are irreducible to the properties of the system's components (i.e., system characteristics are holistic).

Complexity is also a function of the interactions between reality and its observer. As physicist Murray Gell-Mann puts it, a measure of complexity must

include the level of the detail of the description of a system, as well as the previous knowledge about the system and the language used in the measurement of complexity.^[4] Therefore, complexity is not only an ontological characteristic but also a product of the knowledge process. This view brings scientific understanding closer to interpretive and phenomenological epistemologies.

The most significant contribution of chaos theory is to show that "chaos" and "order" are not dichotomous or mutually exclusive categories. In fact, there is order within chaos and chaos within order. This notion defies the Newtonian ontological assumption that there is an ultimate orderliness and determinism in the universe, which can be known in its entirety by the human intellect. Chaos theory also shows that even when the relationships between a system's components are deterministic, the effects of the system may not be predictable in quantitative, precise terms. But there still, is an order within seemingly random system behaviors. This can be predicted and understood in qualitative terms.

Two leading theorists of complexity, Ilya Prigogine and Stuart Kauffman, describe the mechanisms of *self-organization*, which govern the emergence of order from disorder.^[5,6] What Prigogine calls "dissipative structures" are the systems that continually dissipate energy and matter to their environments to maintain their structure. These systems have the tendency to drift toward "far-from-equilibrium" conditions. Under those conditions, they reach certain "bifurcation points," where they fall into chaos or leap to a new, more differentiated order (i.e., they self-organize at higher levels of complexity).

According to Kauffman, biological systems are typically in non-equilibrium states, and they have the tendency to evolve to the "edge of chaos"—a concept similar to Prigogine's far-from-equilibrium conditions. At the edge of chaos, phase transitions take place into more complex forms. This is a self-organizational (endogenous) process, because it does not require an interference from external factors. Emergent complex forms are holistic. For example, once life emerges at the edge of a chaotic state of molecules, its complexity is not reducible to the functioning of the molecules of which it is made.

Prigogine and Kauffman's theories of self-organization have been applied in organizational theory, public administration, and economics. Goldstein derives the conclusion from self-organization theories that organizational change can be a self-generated and self-guided process.^[7] Organizations have an innate potential for transformation, due to the non-linear interactions within them. Organizational change occurs when the organization's components are out-of-balance (i.e., when they are in far-from-equilibrium conditions).

Then new forms of organization emerge. Goldstein and other organization theorists suggest that the theories of self-organization invite us to adopt less control-oriented management philosophies and accept transformational change. Such philosophies, they argue, can increase the probability of successful transformations in organizations and allow the emergence of better organizational forms. Kiel draws similar conclusions for public agencies: Public administrators must embrace the dynamic instabilities and uncertainties, which are the products of non-linear relations in organizations. These dynamics can be the sources of positive transformations in public agencies.^[8]

A group of libertarian, neoclassical economists, such as James Buchanan and Friedrich Hayek, draw parallels between the idea of dynamic self-organization and laissez-faire economics. They describe markets as self-organizing dissipative structures and argue that socialist planning has had devastating effects on economies. Similarly, Kauffman argues that decentralized and flatter organizations, democracies, and free markets work better than their alternatives. When organizations are broken into smaller units, each unit attempts to maximize its self-interest, which, in turn, maximizes the interests of the organization.^[6]

Kellert opposes the libertarian, neoclassical interpretations of complexity.^[9] He argues that chaos theory particularly refutes the notion that laissez-faire capitalism creates optimal solutions. To the contrary, it demonstrates that systems may end up chaotic. Chaos theory also shows that although it is impossible to make precise (quantitative) predictions in chaotic behavior regimes, it is still possible to determine the range and shape of fluctuations qualitatively (chaotic attractors, such as the well-known Lorenz attractor, illustrate this). The theory allows us to determine critical points in an economic system so that we can intervene and make macroeconomic adjustments.

Agent-Based Simulations

Some concepts of complexity theory are applied in *agent-based simulations*, which grew out of the studies on cellular automata, neural networks, and genetic algorithms in computer sciences. Agent-based simulations offer a methodological alternative to the deductive-nomothetic methods of Newtonian science. Newtonian methods strive to simplify reality with a small number of variables, while artificial life simulations generate complex and unique results.

In agent-based simulations, the behaviors of “agents” are simulated using specialized computer software. Agents are individual members of a group, each with its internal states and behavioral rules. They “live” in an environment that imposes some

constraints. In these simulations, the environment is a virtual lattice in which agents are initially placed at certain locations and are let move around and interact with other agents, according to initially set rules. Agents organize themselves into dynamical patterns, collective structures, on the lattice.

Epstein and Axtell’s study is the most comprehensive example of the applications of agent-based simulations in the social sciences.^[10] They simulated a society whose members (agents) were imbued with a set of economic, cultural, and reproductive rules. The agents conduct economic transactions, compete with each other to survive, pollute their environment, form cultural groups, go on wars against other groups, reproduce, and die. Epstein and Axtell’s simulations show that simple equations (behaviors of individual agents) can generate complex behaviors, and that internal dynamics of systems can generate complex, orderly, and chaotic patterns. Social structures emerge through a self-organizing process of individual interactions. Collective structures, once emerged, are not decomposable; they are holistic and are sustained beyond the life span of the agents that generated them.

According to Epstein and Axtell, the method of agent-based simulations can be the basis of a unified and evolutionary social science, which they call “generative social science.” In generative social science, evolutionary simulation models would replace nomothetic explanations and idiographic descriptions. Its focus would be on the behaviors of individual agents, and the processes in which collective structures emerge.

Epstein and Axtell also draw the conclusion from their simulations for economic theories that the aggregate, decomposable models of neoclassical economics are inappropriate. The neoclassical economics uses the rational actor as its unit and aggregates an economy from the behaviors of these actors. It assumes that static equilibria exist, or at least are achievable, and ignores the time dynamics. Epstein and Axtell illustrate that, left alone, markets do not generate equilibrium conditions; instead, they create far-from-equilibrium conditions over time. Society does not necessarily benefit from individualistic competition, because in the process, wealth accumulates through inheritance, and a skewed social hierarchy emerges.

Fractal Geometry

In agent-based simulations, agents are placed in discrete locations on a two-dimensional lattice. This is a limitation for simulating real life, in which things occupy places that cannot be measured in exact terms. *Fractal geometry*, which is considered as the geometry of chaos theory, offers better mathematical modeling tools for simulating real life. Fractal geometry allows

fractional dimensions—“fractal” dimensions between 1 and 2, or 2 and 3—to be used in descriptions. Fractal dimensions represent the degree of roughness, brokenness, or irregularity in an object. In Euclidian geometry, objects are described in terms of straight lines and curves, squares, cubes, and globes, that have finite lengths; and their dimensions can be calculated as whole numbers. There are no perfectly straight lines or perfect squares or circles in nature, however. Benoit Mandelbrot, founder of fractal geometry, studied objects that are irregular in dimensionality, but those irregularities remain constant over different scales, which he called “self-similarity across scales.” Mandelbrot found examples of such self-similar irregularities in nature. The branches of most plants and trees display fractal shapes, for example. In mathematics, fractal images are generated iteratively, by applying the same mathematical rule repeatedly on different scales.

Fractal geometry also demonstrates that the measurement of an object depends on the measurement instrument used. Different resolutions and different scales yield different results in a measurement. Therefore, measurements are not absolute; they are not “objective.” Mandelbrot emphasized that measuring dimensionality depends on the relation between an object and its observer.

AUTOPOIESIS

Autopoiesis is a theory of biological systems. It was developed by the Chilean biologists Humberto Maturana and Francisco Varela in the 1960s and early 1970s. Autopoiesis takes the idea of self-organization one step further and suggests that biological systems are *self-producing* and *self-referential*. It challenges the traditional view that systems are open to the influences from their environments and suggests that all living systems are organizationally closed and autonomous. These systems self-renew and self-create, and their most important products are themselves. A system’s interaction with its environment is a reflection of its organization. The environment is a part of the system, and it is coproduced by the system. In fact, there is no beginning or end to a system; it is a closed loop of interaction.

Autopoiesis theory suggests that the brain is an autopoietic system. It does not simply process information that comes from the environment; instead, it assigns patterns to incoming information. Thus, autopoiesis suggests a constructivist epistemology: The brain does not reflect reality, but it constructs a reality according to its own organization.

Autopoiesis theory has been applied to social organizations and political systems. In Gareth Morgan’s

interpretation, autopoiesis suggests that organizations attempt to achieve a self-referential closure in relation to their environments. They enact their environments as extensions of their own identity.^[11] Actually, most of the problems organizations encounter emanate from the identity they try to maintain. “Egocentric organizations,” which insist on maintaining their identities by imposing them on their environments, end up sustaining unrealistic identities. If an organization sees itself separate from its environment and acts accordingly, it loses sight of the fact that it exists in relationships and that survival is always with the environment, not against it.

Several theorists, including Niklas Luhman and Bob Jessop, drew conclusions from autopoiesis theory for social and political systems and the role of public administration in society. The first general conclusion is that government and public administration are self-producing and organizationally closed systems. The role of public administration is not simply to execute policies but to produce government through complex interactions with its political and social environment. The bureaucratic system aims to preserve its existence and reproduces itself. This poses challenges for democratic governance and administration.^[12]

The second general conclusion is that public administration, or government, cannot control social processes, because other social systems are autonomous too. Therefore, monocentric and hierarchical model of government should be replaced by models of governance in polycentric networks. Such models would be more reflective of realities in which governments do not control other organizations with regulations, but “steer” them through bargaining, negotiating, and participating in markets.^[13]

FUZZY LOGIC

The history of *fuzzy logic*—or, *fuzzy set theory*—goes back to the 1960s, when Lotfi Zadeh proposed it as an alternative to the Aristotelian *sylogistic logic*—or, the theory of *ordinary (crisp) sets*. Unlike ordinary sets, fuzzy sets include elements with partial membership (they are not categorical), and fuzzy logic uses operations that are not available to syllogistic logic. According to Bart Kosko, who is the leading theorist of fuzzy logic today, it challenges a series of “bivalent” assumptions—dichotomies such as black–white, existent–non-existent, either–or, zero–one—which are fundamental to logical positivist science.^[14] Bivalent science mistakenly assumes that its categories correspond to discrete realities and uses a binary mathematics in which numbers are rounded up to achieve discreteness. This is a fallacy, and there is a mismatch between bivalent science and fuzzy reality.

Bivalent science, according to Kosko, is a product of the Western worldview with roots that go back to Ancient Greek philosophy, particularly Aristotle. The Western culture sees binary precision as part of the scientific method. The Eastern philosophies, such as Buddhism, on the other hand, recognize fuzziness and make it a cardinal principle in their understanding of knowledge processes. He asserts that despite all the efforts by bivalent science to make our minds work in a binary fashion, our minds are still capable of knowing fuzzy realities. Eastern societies, because of their openness to fuzzy thinking, have quickly adopted the principles of fuzzy logic and used them successfully to develop more advanced and intelligent industrial products.

There are few applications of fuzzy logic in the social sciences. Among them, Charles Ragin's methodological applications are the most comprehensive.^[15] Ragin sees the applications of fuzzy sets as complementary of what he calls *diversity-oriented methodology*. The commonly used *variable-oriented (quantitative) methodologies* are based on the assumption that every unit of measurement is equivalent, and they ignore the complexity and diversity of social phenomena. Diversity-oriented approach, on the other hand, is concerned with exploring and constructing types and kinds of cases and recognizes causal heterogeneity. In this approach, individual cases are not viewed as collections of analytically distinct variables, but as configurations of sets of membership, and it is recognized that causes may have opposite effects on individual cases.

According to Ragin, fuzzy sets extend and deepen diversity-oriented research strategies. Fuzzy sets allow us to conceptualize diversity not only in the different configurations of set membership but also in the degree of their membership in such sets. As such, they can capture the complexity of realities better and thus help improve the link between theory and data analysis. Fuzzy sets combine qualitative and quantitative assessments in a single instrument. Fuzzy sets contain two qualitative states—full membership of an element in a set (“1”) and full non-membership (“0”)—as well as all the quantitative variations between the two (i.e., partial membership at different degrees; 0.35, 0.50, 0.76, etc.). Fuzzy sets use Boolean logical operations (such as *negation*, logical *and*, and logical *or*) and their own operations (such as *concentration* and *dilation*), which enhances their capabilities.

These enhanced capabilities enable and force researchers to be as faithful as possible to their

concepts and recalibrate them if necessary. Ragin stresses that fuzzy-set applications are not merely mechanical exercises, but they are fundamentally interpretive acts. They prod researchers to pay careful attention to the meaning of concepts; thus, they help find stronger links between theory and research.

Newtonian Paradigm

Mary Ann McClure

*Department of Art, Music and Philosophy, John Jay College of Criminal Justice,
New York, New York, U.S.A.*

INTRODUCTION

Modern science began in the sixteenth and seventeenth centuries with the discoveries of Galileo, Copernicus, and Newton. Conceiving of nature as a machine that works with clock-like regularity, the Newtonian paradigm celebrated order and promised prediction and control. Central to this view of science was the presumption that we live in a universe governed by immutable laws. Human reason was applied to the natural world and a law-like mathematical order was assumed to exist in nature. With Newton's identification of gravity as the force that defined both the motion of the planets and motion on the earth, the same set of universal rules governed the terrestrial and celestial realms.

LOSS OF POWER TO PREDICT

Because all physical systems obey universal laws, accurate prediction “merely” depends on the accurate measurement of the initial conditions. Such confidence in the power of science to predict reached its ultimate expression in the intellectual bravado of Pierre Simon de Laplace, a leading mathematician of the eighteenth century. Laplace claimed that, with knowledge of the initial conditions and intelligence formidable enough to perform the calculations, we could predict the state of the universe at any future moment.

Laplace's claim of omniscience, however, was soon challenged by a compatriot. In 1880, a French mathematician Jules Henri Poincare entered a competition to solve one of the biggest mathematical problems of the day, the “three-body problem.” This problem sounds deceptively simple: “how do you determine the motion of three bodies in space if you know their starting positions?” To his surprise, Poincare discovered that one of the three bodies moves to all intents and purposes in a way that appears to be random.^[1] Yet, the motion is not really random because we know the mathematical equations for it. Poincare identified the phenomenon that would later be called chaos. Chaos occurs when any deterministic system—that is, a system that has laws that govern its behavior—has a solution that is so complex and so irregular

that it appears to be random unless we know a lot of hidden information about what it is doing.

The transforming insight of the Newtonian paradigm had been that the world obeys rules rather than being run by mystic powers or spirits unknowable to the human intellect. Furthermore, if the rules are simple, then you get predictable outcomes. Things that appear to be random, like the spinning of a ball in a roulette wheel, are what they are because they are governed by rules that are incredibly complicated. That is, complicated things are the result of hugely complicated rules. The concept of chaos undercuts this simple Newtonian view of the universe. The world of classical mechanics turns out to be much more mysterious than Newton, or even Einstein, imagined.

Chaos shows that some of the simplest rules you can imagine—simple, rigid, prescribed rules, with nothing random in them, like the rules that governed the motion of Poincare's third body—can generate behavior that is both random and complex. No longer do complicated things have to be the result of complex rules. Furthermore, simple rules can behave in such a complicated way that they do not have a predictable outcome.

SENSITIVE DEPENDENCE ON INITIAL CONDITIONS

Nevertheless Poincare's work was shelved and ignored by the major physicists and mathematicians of his time. Seventy years later, Edward Lorenz, a meteorologist working on mathematical models for the behavior of the earth's atmosphere, inadvertently made a discovery that would bring chaos theory to modern attention. In 1959, he left a room while leaving his computer running. When he was gone, the computer rounded off a few decimal points that resulted in an imperceptible difference in the initial conditions. When Lorenz got back, he discovered a radically different pattern had emerged from this insignificant change. He had thus discovered that insignificant differences in initial conditions, if given enough time, could produce different outcomes. Lorenz had identified a distinguishing characteristic of chaotic behavior: sensitive dependence on initial conditions.

Consider the motion of the earth around the sun. Its behavior, manifesting Newtonian regularity, is captured by a linear mathematical equation and is easy to predict. Linearity implies proportionality: small causes create small effects. If something pushed the earth slightly out of orbit, the result would be a new orbit close to the original. Chaotic systems are, however, non-linear: small causes can create big effects. In a chaotic system, the rate of change is expressed by a non-linear equation; in a non-linear world, exact prediction is both practically and theoretically impossible. For example, for insect populations, when the system is in a chaotic state, two initial populations that differ, say, by less than 1% will have different numbers in just a few years. Thus, if the initial configuration of a chaotic system is changed even slightly, its future behavior is altered radically.^[2]

Pointing out the consequences of his discovery, Lorenz observed, “It implies that two states differing by imperceptible amounts may eventually evolve into two considerably different states. If, then, there is any error whatever in observing the present state—in any real system such errors seem inevitable—an acceptable prediction of an instantaneous state in the distant future may well be impossible.”^[3] In practical terms, for Lorenz’s particular project, it also meant that weather is inherently unpredictable. Long-range forecasts are not possible. No matter how complex our models become, or no matter how accurate our measurement of the initial data, there is a limit beyond which we can possibly accurately predict.

In most cases, Newton, of course, had it right. We have been using him for the last 300 years to predict the motion of heavenly bodies, the flight of space craft, and also more mundane motions. However, if you fine-tune Newton, you find something a little different. Newton says that *if* you know the initial conditions perfectly, then you can predict anything in nature. The problem is the “if.” Variables within a system can be fixed only within some finite degree of accuracy. For example, it is impossible to pin down the position of a particle in space with perfect accuracy. In a chaotic system, these tiny variations get amplified. Lorenz called these amplification of the smallest differences, the “butterfly effect.” That is, the flapping of a butterfly’s wings in Chile leads to a tornado in Japan.

Admittedly, the predictive powers of modern science had already been challenged by quantum theory. But quantum uncertainty focuses on activity on the microlevel. Furthermore, the effects of quantum fluctuations are extremely small and tend to cancel each other out. But with chaos theory, phenomena at the level of ordinary everyday reality have become unpredictable.

ORDER WITHIN CHAOS: STRANGE ATTRACTORS

But within the unpredictability and apparent randomness of chaotic behavior, there is order, a hidden structure that is mapped out by strange attractors. Strange attractors model the behavior of chaotic systems in phase space. Phase space charts the changes in the system’s behavior over repeated cycles. An attractor is simply any point within an orbit that seems to attract the system to it. Attractors are labeled “strange” when their orbits wander in complex and unpredictable ways. For example, coordinates that are close in numerical value can have orbits far apart. But the orbits of the strange attractor always stay within a certain path so that the shape is quite distinct. Measuring a transverse cross-section of the volume of any strange attractor will always yield a fractal.^[4] A fractal is a form characterized by recursive symmetries that occur when the same pattern is repeated in different sizes and shapes. This characteristic of strange attractors links chaos theory to topology and the geometry of fractals developed by Benoit Mandelbrot.

Part of the power of chaos theory lies in the fact that an amazing range of diverse systems can be modeled as strange attractors, including the erratic eye movements of schizophrenics, variations in cotton prices, and outbreaks of infectious diseases. Chaos theory looks for changes in scale and follows the behavior of the system as iterative (the result of a calculation being feedback into the formula again and again) formulae change incrementally.

From this perspective, a proper explanation is one that is able to model large-scale changes through the incremental evolution of a few iterative equations. For example, in a study of the eye motion of schizophrenics, the emphasis of the model is not on the eye so much as the equations that, when iterated, would produce wandering orbits equivalent to the eye’s movement.^[5] From this point of view, it is coincidental that the system in question is an eye. It could equally well have been the fibrillation in the heart or the fluctuation in cotton prices. Models do not take into account a system’s specific mechanism. This represents a different concept of explanation than that given in traditional science where to explain means to uncover the system’s specific mechanism that causes behavior. Here you are producing a mathematical model that simulates the behavior. Chaos theory looks to the mechanism that will show how patterns arise alongside unpredictable behavior, providing an understanding of “how it happens” rather than “why it had to happen.”

To sum up, a chaotic system is characterized by deterministic randomness. Deterministic because the chaotic behavior itself arises from intrinsic causes that can frequently be expressed in simple equations and

whose order can be mapped by strange attractors. Randomness because the behavior remains irregular and unpredictable.

PRESUPPOSITIONS OF THE NEWTONIAN PARADIGM AND CHAOS THEORY

Chaos theory operates on a different set of assumptions than those of the Newtonian paradigm. First, in Newtonian paradigm, problems or events are linear. That is, small causes create small effects, and scientific theories have to be quantitative to even be considered theories. But chaotic systems are always non-linear systems in which small causes can create big effects. Because quantification is not possible with dynamic systems, chaos theory must turn to qualification. It asks—what does the system look like as it moves through changes?—and answers by watching the strange attractor being displayed on a screen. Thus, the study of chaos yields qualitative predictions for systems where detailed quantitative predictions are not possible. Qualitative theories become as important, if not more so, than the quantitative.

Second, from the Newtonian perspective, objects are considered to be independent of scale. Measuring a room with a yardstick or an inch ruler produces the same result. But chaos theory deals with the complex, irregular forms of turbulence and fractal geometry that are scale dependent. Measuring a rugged coastline with a mile scale or an inch scale produces different results because the inch scale is always going to capture more length.

Third, the Newton paradigm employs a foundationist approach that focuses on individual particles or units. To study a system is to follow the unit through time, adding the behavior of the units. This is a reductionistic method. One isolates the appropriate unit and understands the mechanism that binds the units to the larger whole. To understand how a clock works, you break it down into its simplest parts. This reductionist

spirit still pervades modern science. A salient example is the reductionist program of molecular biology, which has achieved its fullest expression in the human genome project.

In contrast, for chaos, the individual does not matter. Remember Poincaré's work on the three-body problem. Reductionism holds that the laws affecting the parts give the behavior of the whole. But the action of two bodies is linear and of three, chaotic. Thus, reductionism is contradicted. Chaotic behavior is governed by the strange attractor that affects the system as a whole. The emphasis shifts from individual units to recursive symmetries between scale levels.^[6]

In conclusion, the history of science dominated by the Newtonian paradigm has been the struggle to impose order on a world of turbulence and disorder, a world where the only straight line is one that man has introduced. Chaos science produces a new geometry that shows there is order within disorder. It destabilizes the order-disorder dichotomy, revealing a territory that cannot be assimilated into either order or disorder. Chaos theory represents the revisioning of the world as dynamic and non-linear, yet predictable in its very unpredictability.

No Child Left Behind Act of 2001

G.L.A. Harris

*Mark O. Hatfield School of Government, Portland State University,
Portland, Oregon, U.S.A.*

INTRODUCTION

The No Child Left Behind (NCLB) Act of 2001 became federal law with great fanfare and promise to overhaul the public school education system in the United States. According to the Act, public schools must demonstrate adherence to well-defined educational principles.^[1] The purpose of this essay is to show the evolution of the modern public school reform movement in the United States, the movement encapsulated in its present day form as the No Child Left Behind Act of 2001, assertions by both supporters and detractors of the Act, and the growing pains experienced by states as they attempt to navigate the implementation process.

OVERVIEW

The NCLB Act of 2001 is comprised of Titles I–X and consists of the following: Title I, Improving the Academic Achievement of the Disadvantaged; Title II, Preparing, Training and Recruiting High Quality Teachers and Principals; Title III, Language Instruction for Limited English Proficient and Immigrant Students; Title IV, 21st Century Schools; Title V, Promoting Informed Parental Choice and Innovative Programs; Title VI, Flexibility and Accountability; Title VII, Indian, Native Hawaiian and Alaska Native Education; Title VIII, Impact Aid Program; Title IX, General Provisions such as the Unsafe School Choice Option; and Title X, Repeals, Redesignations, and Amendments to Other Statutes such as the McKinney-Vento Homeless Education Assistance Improvements.

The NCLB Act purports to focus on what works by emphasizing proven educational programs and practices, reducing bureaucracy and increasing local flexibility, increasing accountability for student performance and empowering parents. Participating states in turn must align their own school districts' policies to the federal guidelines of the Act.

First, the NCLB Act requires annual report cards as performance reports. The report cards will reflect the degree to which a school is accountable by its performance on state designed annual assessments for reading and mathematics in grades 3–8. Reports will enable parents, educators, administrators, policy makers, and

the general public to track the performance of schools. Such assessments would reflect each state's ability to hold schools and districts accountable for student achievement standards the state mandated; student, school, and district progress annually to meet the standards; and the amount of federal aid in financing school reform.

Schools that meet or exceed states' standards would be eligible for academic achievement awards. However, those schools that fail to "meet the grade," would first be targeted for assistance, then remediation, and finally restructuring.

Second, NCLB promises flexibility and thus greater accountability in order to encourage more control of the decision making at the state and local levels where educators are more likely to be familiar with their students' needs. State and local jurisdictions in turn can spend at least half of the federal funds earmarked for other school programs for NCLB activities including the hiring of new teachers without federal approval.

Third, parents would gain greater control over which schools that their children attend. Parents could exercise an option to transfer their children from a school that failed to meet state standards for two consecutive years to a better performing public school within their districts. Such options would also extend to the children of low-income families who attend low performing schools that fail state standards for three years. Children who transfer may receive supplemental educational services such as tutoring, after-school services, and summer school. Further, students in poor performing schools that their parents deem to be unsafe can transfer to safer, better performing schools within their districts.

Finally, the Act would support educational programs or techniques that come from rigorous research with opportunities for educators to upgrade their skills through professional development. The Act's four-pronged emphasis on accountability, flexibility, parental choice, and research would provide the hallmarks for success.

THE BEGINNINGS

NCLB's roots are unclear at first reading. They appear to emanate from four earlier attempts at educational

reform. In a speech on April 22, 2004 at Harvard University's Kennedy School of Government, Education Secretary Rod Paige described the *Brown v. the Board of Education* May 17, 1954 decision as akin to the NCLB Act of 2001. He cited the vehement resistance of the time as an educational divide that is "cruel, vicious, demeaning, disrespectful and degrading." He went on to say that "I believe that when a child is left behind by an education system that is an injustice that affects us all. It is intolerable."^[2] Scott (see p. 179 of Ref.^[3]) also points to the U.S. Supreme Court's ruling in *Brown v. the Board of Education* (347 U.S. 483, 1954). Scott (see p. 179 of Ref.^[3]) establishes the *Brown* case as the starting point in modern school reform by the decision's holding that "racial separation adversely affected self-esteem, which reduced motivation and consequently retarded the educational and mental development of Negro children." Nowhere is such injustice prevalent and a desire for the "quality of education stronger" than in African American communities. (See p. 203 of Ref.^[3].) Scott cites Henninger (2003) in a 2003 poll by Public Agenda which found that 82% of African Americans parents, for instance, desire efforts to promote a quality education.

The Elementary and Secondary Education Act (ESEA) of 1965 marked a second attempt at closing the education achievement gap.^[4] In NCLB such efforts were not directed just towards bridging the gulf that existed between black and white children but also in achieving educational parity for the nation's poor and disadvantaged youths through federal funding of public schools K-12 educational programs.

However, following some 20 years of awkward and repeated trials at educational reform, including school busing during the 1970s, a 1983 report entitled "A Nation at Risk: The Imperative for Educational Reform" served as the third basis for NCLB. The report's authors accused the nation's public education system of being "a rising tide of mediocrity." (See p. 5 of Ref.^[5].) Mediocrity, according to the report, "threatens our very future as a Nation and a people." (See p. 5 of Ref.^[5].) Many reformers were legitimately concerned with the history in many school districts—especially urban schools—of students who graduate from high school unable to read and write at the minimal level; of teachers who lack the skills, concern or drive to reach students; of special education placements that seem to follow racial categories; and of rigid tracking. This national wake-up call, they hoped, would "generate reform of our educational system in fundamental ways." (See p. 6 of Ref.^[5].)

Finally, much of NCLB grew out of provisions written into various proposals that became laws after 1965. With the Improving America's Schools Act (IASA) of 1994,^[6] a revision of the Elementary and Secondary

Education Act of 1965,^[4] required that states develop assessments in keeping with local standards for reading, mathematics and science at all grade levels. The officials also required that state administrators use the data derived from assessments to track student performance improvement and to identify low performing schools.^[7]

NCLB crystallized national thinking about education reform as change that must give greater responsibility to local administrators under state government authority. Unlike its predecessors, the Act gives states and local districts flexibility in choosing how to spend federally allocated funding for education. States and local districts must set, adhere to and meet or exceed the state standards for student achievement. The standards and actual performance would lead to greater accountability. Parents, too, could exercise a wide range of options in hoping to secure the best education for their children. Teachers might pursue continuing professional development to ensure that they could employ proven techniques. In essence, the NCLB Act would attempt to "foster an environment in which every child can learn and succeed."^[1]

THE PROS

Proponents of NCLB point to many features of the Act's goal to maintain high standards. First, the Act recognizes that low achievement may frequently reflect education programs of compromising quality and instruction by inadequately trained or uncertified teachers.^[8] Testing and accountability through the Act could "illuminate problems that would otherwise go undetected, allowing teachers to tweak their lesson plans or add hands-on projects." (See p. 481 of Ref.^[8].) Testing not only would serve as a tool for teaching and learning but also good educators would not need to teach to the test or depart from individualized instruction. Educators would have the latitude to structure lesson plans in ways that motivate students.

Second, accountability would empower parents. Parents would get help in making decisions about where to help their children gain an education of higher quality. Annual report cards would separate the best performing schools from the lowest performing ones. State assessment programs would enable officials to raise achievement levels for all students. States would be able to close the achievement gap of low performing students, particularly those from low income and minority groups.

Further, proponents argue that the accountability systems NCLB called for already exist. Many schools "are beating the odds" according to Strahan (see p. 297 of Ref.^[9]), who cites case studies of four schools. Collectively, these case studies have highlighted the

success of three specific paths towards education reform.

First, academic engagement of students in meaningful classroom tasks fundamentally influences student achievement. Second, based on a 1998 Sanders and Horn report from the Tennessee Value-Added Assessment System,^[10] Strahan sees the quality of the teacher as another key contributing element in academic achievement. Strahan discounts such demographic variables as race, socioeconomic level and class size as “poor predictors of student academic growth.” (See p. 298 of Ref.^[9].) Third, collective effort by teachers appears to go a long way to improving academic achievement. Collective faculty efficacy or “the extent to which teachers have the belief that they can work together to produce effects” was a significant predictor of student achievement in that teachers “shared perception over time” helps to shape a child’s environment in school. (See pp. 298–299 of Ref.^[9].)

However, Strahan quickly notes that teachers may not necessarily teach to a particular program. While academic engagement in meaningful classroom tasks, the quality of teachers, and collective efficacy of the faculty have proven to be effective, the most successful schools are those that tend to use curricula in a way that accounts for their students’ needs.

THE CONS

Although NCLB received overwhelming bipartisan support, critics argue that the Act will serve only to label schools as failures while failing to provide those same schools with the resources or support necessary to increase achievement.^[8] Many opponents also question the validity and reliability of the Act’s assessment strategies in reforming the public school system.^[8]

Failure and success, as well as the assessment strategies called for in the Act, center on systematic student testing. Standardized testing has existed for some time and has gained popularity because Americans have come to accept that reward and punishment are effective tools to use in achieving any goal.^[11] While these testing-based assessment strategies may elicit temporary compliance and some evidence of immediate achievement, they could do so at significant costs, say critics. Most notably, research suggests that the more rewards or punishment are used as a way of inducing people to engage in an activity, in this case, to improve student’s performance on standardized tests, the more that these students will lose interest in what has to be accomplished in order to receive the reward or escape punishment.^[11] These research findings relate to the carrot and stick control that standardized tests provide. Testing becomes a high-risk condition for students. The Act provides that students may be held back in

grade levels when their test results in low scores, prevented from graduating based on low scores, and their teachers evaluated on students’ test scores with salaries increased or decreased accordingly.

Critics point out the fallacy of standardized testing. They show that such methods were originally designed and intended for the homogeneous population in France as a way of identifying children who were slow learners so that those slow learners could be given remedial work.^[12] The French government’s attempt at using the most objective measure avoided the prejudices of teachers who might be inclined to identify such students as mentally impaired. But it was the American version of this imported measure through Stanford University psychologist Lewis Terman who revised the Alfred Binet measure to establish norms for American children. However, the American tests were never designed to reflect differences among a heterogeneous population. In essence, the American version did not serve to bring slow learners up to par, becoming instead a gauge to categorize, isolate, and even ostracize people in school. Wade and Tavis citing the work of Gould (1996), claimed that the testers not only failed to consider the heterogeneity of the American population but that such diversity would also reflect differences in background and experience for which American standardized tests are not purported to measure.

Critics see the continued justification for the use of standardized tests as relatively inexpensive and easy to implement.^[13] These critics attack policy makers who favor simplistic and cheap solutions over complex and expensive ones. These critics argue that educators should emphasize more powerful and longer-term methods such as curriculum-focused professional development. Further, civil rights activists in both New York and Texas have challenged NCLB in court, arguing that this kind of high stakes accountability system has served to discriminate against poor and minority students. Researchers and educators believe that standardized test-guided systems narrow curricula and limit teachers’ flexibility and creativity.^[7] According to Price,^[14] standardized tests linked to student classroom performance threatens academic freedom. Moreover, a survey in 2003 of teachers in the Memphis and Shelby County Tennessee school districts on high stakes testing revealed that many teachers felt restricted in the classroom due to the undue demands that a heavy testing schedule places on classroom time.^[15] Other teachers have complained of the cheating in such testing or a systemic exclusion of weak students on test days in order to raise the average test scores as well as rendering assistance to students during which time test answers are changed.

Accordingly, accountability standards have created an environment where teachers and administrators

face discipline for violating security rules for standardized testing. A school principal has opted for retirement to escape the wrath of a disciplinary hearing involving charges of impropriety on her school's Tennessee Comprehensive Assessment Program (TCAP).^[15]

Critics charge that the NCLB Act only amounts to a "collective spine counting" by using the conclusion of scientifically based studies to identify patterns of student achievement. (See p. 304 of Ref.^[9].) Use of such scientific methods therefore cannot begin to capture the essence of meaningful reform. Accordingly, students, teachers, and administrators experience this process at a much deeper and personal level. What is unique about the schools profiled in the Strahan^[9] article is that they used given mandates for accountability but accomplished student achievement in their own ways, even exceeding expectations. In other words, they applied local solutions to solve local problems.

Opponents note the pattern of educators to use tests to administer a one-size-fits-all style of education while discounting individual attention and instruction.^[8] Opponents believe that educators will "teach to the test" while emphasizing test taking strategy at the expense of critical thinking. (See p. 482 of Ref.^[8].)

Opponents also have confidence that accountability need not always be as NCLB orders, a high-stakes testing report card. There are other ways of measuring accountability such as "using presentations and portfolios to gauge the students' ability to connect ideas, think critically and use information meaningfully." (See p. 483 of Ref.^[8].) The fear is that accountability standards based on high-risk standardized testing will encourage states to use such test scores to confirm their biases or findings.

IMPLEMENTATION AND REACTION

Many states have found the provisions of the NCLB intrusive. For instance, Virginia's House of Delegates recently approved a resolution requesting that Congress exempt the state from the Act's mandates.^[16] Jim Dillard, Republican head of the state's House Education Committee, considers the NCLB Act to be "utopian nonsense" and went on to say that "not only is it a massive federal intrusion, it is simply unworkable." (See p. 1 of Ref.^[16].) Utah also approved a similar measure as Virginia to opt out of the law's requirements although the state finally adopted a compromise to prevent the state from making expenditures on the law. Vermont's governor has also signed a similar ban.

Other states like Maine and New Hampshire have also proposed not using state funds for the law while Arizona, Hawaii, Minnesota, and New Hampshire have proposed measures to opt out of the law altogether.

State protests have already resulted in the federal government's reconsideration of testing requirements. The same tests will not be used for both native and non-English speaking students.^[16] Further, federal officials express willingness to negotiate teacher requirements in rural districts. And, governors like Jim McGreevey of New Jersey stated that, "Governors would look forward to working cooperatively in achieving the goals of NCLB. Yet, when you have some of the finest school districts in the nation being designated 'in need of improvement' or 'failing' because of an arbitrary benchmark, the legislation needs an agonizing reappraisal." (See p. 2 of Ref.^[16].)

Money became another contentious implementation issue. Some experts assert that plans tying federal funding to student performance make sense, but, cutting funds in poor performing schools does not.^[14] The carrot and stick strategy reinforced with funding, opponents argue, punishes those schools that need the funding the most and reinforces the notion that certain groups of people are beyond help. Many also view labels as "underperforming" or "failing" as synonymous with "undeserving." For example, the Act may aim to prevent schools from neglecting hard-to-teach groups. Many schools, such as Midwood High School in Brooklyn, New York, win science awards and have high graduation rates, but through the NCLB, state education departments label the schools "in need of improvement" because students fail to achieve the state's assessment standards. (See p. 2 of Ref.^[17].)

Many problems have surfaced from the actual implementation of the Act as it relates to compliance for testing. For example, many parents of children in New York's lowest performing schools, according to reports, were given only a few days to respond to the opportunity for moving their children to another, higher performing school.^[17] Available space for the students who wanted a transfer also became a problem. Students in Chicago encountered space problems with 270,000 students qualified for transfers, discovering that only 1097 spaces were available.

The most vociferous protests have come from teacher unions. Some threatened litigation against the U.S. Department of Education. The unions saw the Act's requirement, such as requiring that all teachers be qualified to teach in their respective subjects, as unreasonable. And, the teachers insist that test results could be attributed to a number of other factors including class size instead of teacher competency.

OPPOSITION DOES NOT MEAN COMPROMISING ACHIEVEMENT

Opponents contend that challenging NCLB, and thus standardized tests, does not mean they oppose high

academic standards.^[14] The challenge means that they oppose using such testing as the sole basis for reward or punishment. NCLB opponents believe that a more effective strategy is to support families and provide the resources public schools need to enable students with different needs to achieve at all academic levels.^[14]

Opponents point to the increasing pressure that states face to deliver improved test results or risk the loss of funding due to accountability standards and emphasis on standardized testing under the Act. Another approach might be evidence-based models of teaching to close the achievement gap, particularly among poor and minority students. But the literature suggests that Title I funds, estimated by the U.S. Department of Education in 2001 to be between \$400 and \$500 per student, are insufficient to close the gap alone.^[18]

Title I funds needed, in the form of preschool programs designed for early intervention, can cost up to 20 times the typical Title I allocation. Reduction in the size of classes could cost up to three times the allocation. Quality comprehensive school reform programs like Success for All, could require up to 20% more funds. Borman^[18] believes that much higher funding to these programs entails a greater and stronger commitment at the federal, state and local levels of government. This commitment must be long-term, coordinated, and systemic. Further, by investing in preschool, summer school and other school programs, the achievement gap can even be eliminated and produce long-term benefits for society.

In the meantime, according to Price^[14] with Schemo,^[19] “states are scrambling to rig tests results by lowering test standards so that they can claim academic improvements, though the federal Department of Education has vowed to end such practices and has declared such test cheaters enemies of equal justice and equal opportunity.” (See p. 7 of Ref.^[14].)

Realizing that states will have to expand their assessment programs, some resulting in the testing at additional grade levels, federal officials have promised to help cover the costs of developing these assessments. However, for the time being, states must absorb this additional financial burden without immediate relief.^[7]

UNINTENDED CONSEQUENCES

Many educators fear that the provisions of NCLB may have unintentional consequences. These include administering only certain mandated tests, manipulating data and teaching to the tests. An emphasis on testing could rob students of a well-rounded educational experience. Evidence of this tunnel vision approach to compliance has already appeared.^[7]

Some states have had to game the high risks in testing. State officials have installed a variation of compliance by administering only those tests mandated by the Act. These officials hope that stopping all but required tests will motivate students to focus on the required tests and succeed. The variation state officials have developed is to teach and test to the real test.

NCLB has provoked devious bureaucratic strategies often involving fraud as well. A Pittstown, Pennsylvania mother in January, 2004, grew increasingly concerned about her daughter’s receipt of unusually high test scores that she believed did not reflect her child’s mathematical ability.^[20] Suspicious, the mother asked that her child be retested. The child’s performance on the second test did not replicate the result of the first and the mother admitted that her daughter frequently “tries to get out of doing homework.” (See p. 5a of Ref.^[20].) The mother also discovered that the initial test showed answers that were originally marked wrong, erased, and changed to mark the correct answers.

The unduly stressful atmosphere created by the Act provoked another case in Connecticut. The Connecticut Education Association hired an independent economist to examine current data and to project how the Connecticut schools would fare under NCLB’s mandate of annual yearly progress (AYP).^[21] The intent was to help anticipate the effects of AYP in one of the highest achieving states in the nation. Even though the projected results were hypothetical, they were surprising. In the study, almost one-quarter of Connecticut schools would fail to meet the annual yearly progress standards. In essence, 155 elementary and middle schools and 88 high schools would be labeled “in need of improvement,” (see p. 47 of Ref.^[21]) and over the life of the Act or 12 years out, an astonishing 744 of the 802 elementary and middle schools or 93%, would fail to make their adequate yearly progress.

The Connecticut case reveals the questionable realism of the AYP formula. The formula fails to consider the differences among schools. The formula does not consider where a school starts and how quickly that school must reach its goal. Some schools, starting far behind others will need far more time to reach the state goals. Differences among schools put into question the AYP formula as the best gauge of student progress and thus school effectiveness.

Under NCLB, schools stand to lose significant funding if they fail to show mandated annual progress. However, this kind of pressure also supports those studies that indicate that such high stakes testing approach leads to rampant cheating and where poor performing students are reclassified as either disabled or special education students by excluding them from a school’s aggregated tests scores.^[22]

If this is the length to which some schools are willing to go in the quest for high achievement, then the NCLB Act of 2001 has forced an increasing number of cash-strapped states to do whatever is necessary to, in essence, “make it happen.” This blind eye at compliance then appears to further reinforce what other reformers have charged the public school system bureaucracy of doing. Teachers therefore implicitly understand that they must “teach to the test,” and in doing so, discourage critical thinking.

CONCLUSIONS

The NCLB Act of 2001 was created to redress the growing inequities and mediocrity that have culminated to define the nation’s public school system. The NCLB Act, it is hoped, would provide much needed resources to schools to achieve four clear cut goals: accountability for academic performance through annual reporting; built in flexibility for control at the local levels; increased parental involvement and thus school choice; and utilizing well-proven methodologies that are scientifically based. Continual assessment by using standardized tests is the cornerstone through which these goals can be achieved.

Proponents point to the Act’s use of high standards as a gauge to increase academic achievement as well as accountability. Small, but remarkable successes have also been reported for schools that are “beating the odds.”

Critics argue that the Act falls short by over relying on standardized testing as the tool to measure academic performance. Further, this one-size-fits-all style of education forces “teaching to the test” and discourages critical thinking in an attempt to preempt desired results.^[7]

An equal number of researchers also believe that standardized tests used to predict how likely students are to perform in subsequent educational settings and thus a school’s effectiveness, is deceptive.^[23] This can be attributed to what some researchers call “confounded causation” which they believe to consist of three main factors: what is taught in schools, a student’s native ability and out-of-school experience. However, it was the third factor that researchers found most troubling. Their argument: if children come from socioeconomically advantaged families and stimulus-rich environments, then they were more likely to succeed on items on standardized achievement tests than will other children whose environments do not mesh as well with what the tests measure.

These unintended consequences have not only resulted in some states forfeiting the right to funding that accompanies the Act’s implementation, but such action has forced the federal government to revise its

approach. One such revision includes negotiating teacher requirements in rural districts.^[16] However, some states are reshuffling priorities instead to avoid opting out of their share of the \$12.7 billion of federal funding promised by the Act.

The longitudinal study of 24,599 eight grade students by the U.S. Department of Education’s National Center for Education Statistics since 1988 shows that one consistent predictor of student achievement regardless of race and/or socioeconomic status is parental involvement.^[24,25] If this is the case, then the implementation of the NCLB Act of 2001 may be misguided and efforts should be expended on encouraging parents to invest time in their children’s education at home to help adequately prepare them for learning in school. According to Ramey and Ramey,^[26] for instance, such parental involvement is key to educating ones child.

Research also shows that early intervention at the preschool level is one proven strategy to help narrow the achievement gap and thus benefit society in the long run.^[18] However, under NCLB, and in the current era of austerity, educators and administrators might be tempted to go the path of political expedience at the expense of a quality education for children.

In theory, the NCLB Act of 2001 is perhaps the most revolutionary legislation to emerge in five decades. Its focus on accountability; flexibility and in turn local control given adherence to states’ assessments; enhanced parental control through annual report cards; and emphasis on scientifically based programs and techniques to improve students’ learning and performance; is to be commended, for without such established parameters, there would be an uneven handedness in its application and vast differences in the quality of education will exist from state to state and from school district to school district. However, the Act’s implementation becomes unwieldy as “the devil is in the details” and thus in its practice.

The federal guardians charged with the implementation of the NCLB Act of 2001 may be forced to reconcile some, if not all of the Act’s provisions, by taking a more practical approach as is already evidenced from the number of states, who despite their budgetary woes, have made the decision to opt out of the Act and thus lose needed funding. A re-examination of the extent to which states and in turn school districts may differ or have unique circumstances may be warranted. Further, and according to research, the most successful schools are those which, while meeting student achievement, are allowed to be flexible in their application. In other words, having a “one-size-fits-all” approach is impractical and in the long run serves to benefit no one especially the children for which the Act is intended.

Non-Monetary Incentives and Productivity

Hedy L. Isaacs

Department of Government, University of the West Indies, Kingston, Jamaica

INTRODUCTION

Non-monetary incentives refer to tangible and intangible means of motivating and rewarding employees. The humanistic philosophy that is the basis for using these incentives is that employees do not conform to the “men as machines” stereotype. Employees are social beings and non-monetary incentives may encourage them to achieve their own personal goals as well as their organization’s goals more readily, effectively, and efficiently. Agencies may use non-monetary incentives that are linked to employees’ needs and expectations about their job contents or contexts to accomplish their agencies’ goals. Non-monetary incentives may also be linked to employees’ expectations to balance their work lives with their personal lives. Their expectations may depend on the meaning and purpose of work. Non-monetary incentives are integral to the social and managerial aspects of an agency’s productivity improvement program. Agency managers have the task of identifying and developing appropriate non-monetary incentives that satisfy the totality of needs of the agency’s human capital. Humanistic management values, strategies, and ethos that couple employees’ needs, expectations, and attitudes with employees’ aptitudes, abilities, and knowledge in a particular job context may provide scope for improving employees’ productivity.

MOTIVATING EMPLOYEES

Individuals bring the totality of their needs to the workplace. How agency managers address these needs requires their awareness of, and sensitivity to, employees’ behaviors. Research conducted by behavioral scientists on the underlying motives for individual behavior, links the satisfaction of specific needs to individual motivation. The research results have gained prominence and may provide public managers with some signposts in their search for appropriate non-monetary incentives for public sector employees.

The work of pioneers Abraham Maslow, Elton Mayo, and Douglas McGregor, as well as more recent researchers—Frederick Herzberg, Clayton Alderfer, and David McClelland—has common themes: individual behavior is goal directed, and individuals’ needs

and expectations, if not satisfied, affect their performance on the job.

Maslow found that individuals have a hierarchy of needs. Individuals are continually developing and moving from one level of motivation to the next. When individuals satisfy their *basic* or physiological needs, the higher needs become evident. For example, hungry employees will not perform satisfactorily. Their goal will be to eat, and their motive will be to find food. *Safety* needs, commonly referred to as security needs, are at the next level. These needs are manifested in an employee’s desire for predictability and for protection from physical danger at the workplace. The *social* needs, at the next level, are manifested at the workplace by the employee’s need for secure social relationships. It is arguable that attempts to break up or to control groups at the workplace may lead to antagonistic and unproductive behavior by employees. *Esteem* or egotistic needs, at the next level, relate to our desire to be self-confident, to experience independence, and to be respected, appreciated, and recognized. All employees have this need, which, if properly used in the workplace, may result in higher levels of performance. The need for self-fulfillment or *self-actualization* is the highest level of need. At this level, employees are striving to achieve their full potential. According to Maslow’s approach, when managers recognize that these five levels of needs exist and use them effectively, worker productivity is likely to increase.

More research has disputed the view that an individual’s needs are satisfied in a systematic manner, as implied by Maslow. Clayton Alderfer accepted the view that individuals have similar needs to those Maslow identified. He found that individuals have three sets of needs: *existence*, *relatedness*, and *growth*. *Existence* needs correspond to Maslow’s physiological and security needs. *Relatedness* corresponds to social needs, and *growth*, to esteem and self-actualization needs. By placing these needs along a continuum rather than a hierarchy, employees can therefore deal with two sets of needs at the same time. Alderfer’s growth view holds that when some motive reaches some level of satisfaction, then a new set of motives is triggered.

McClelland’s contribution focused on the individual’s need to achieve. He identified the characteristics associated with individuals who have a high need to achieve. For example, individuals who believe that they

Individual's Goal To Balance Work Life and Personal Life

Fig. 1 Sources of employees' needs and expectations.

can make a difference to outcomes have a high need to achieve. These individuals are always thinking about ways to improve outcomes and face "head on" the challenges of solving work-related problems. If agencies stymie the efforts of high achievers, these employees will leave for other agencies that are more accommodating of their need to get things done.

Frederick Herzberg found that the job itself is a potentially motivating force. When individuals are satisfied with their jobs, they are also likely to be satisfied with their job environment.

Elton Mayo's pioneer research, however, found that employees were not simply motivated by the job itself, but by the human aspects of their work. Mayo's "Hawthorne Studies" found that pay and safe working conditions were not the only concerns of workers. Employees in Mayo's studies were also concerned about self-actualization, self-esteem, their ability to be in control of their jobs/to work without close supervision, to problem solve job-related issues when necessary, and to form and maintain informal relationships.

Managers' assumptions about human nature are also likely to affect individual behavior and productivity. Douglas McGregor found that if managers expect employees to be lazy and unproductive, this could be self-fulfilling, as employees are likely to conform to these expectations. Conversely, when employees are assumed to be self-directed, ambitious, and industrious, they are likely to be more productive.

According to Hersey, Blanchard, and Johnson,^a the assumptions that are made depend to a great extent on the values espoused by agency managers. "humanistic-democratic values" underpin managers' assumptions that employees are motivated by affiliation, esteem, and self-actualization needs. "Bureaucratic values" underpin managers' views that employees are motivated solely by their basic needs and by the conditions under which their jobs are performed. These values affect staff outputs and outcomes.

The totality of an employee's needs is complex and wide ranging. These needs may relate to the job environment, the job, or to management's attitudes. An employee needs a quality of work life that provides a comfortable, healthy, and safe work environment. An employee also needs interesting and satisfying work—to be an active participant in solving work-related problems and to be recognized, respected, and provided with opportunities to achieve and be competent.

Individual employees have different needs at different times. These needs, or most of them, have to be identified and satisfied. Managers, therefore, play a critical role in improving productivity. Their attitudes and approaches to managing their agencies' most valuable asset, the human capital, are determinants in productivity improvement. Their approach requires

^aFor detailed discussion see Ref.^[1].

Table 1 Employees' needs and expectations

Source	Needs and expectations
Individual	Balance work life and personal life
Job related	Work that is challenging, satisfying, and empowering
Job environment related	Quality of work life that encourages productivity
Management/supervision	Use talents, be creative/innovative to accomplish work goals
External environment	Agency awareness of cultural differences and of employees' personal needs in a changing environment

that they show concern for individuals' expectations and needs, as well as provide the incentives that satisfy these needs. The social and managerial dimensions of an agency's productivity improvement program may offer some guidance to managers.

PUBLIC PRODUCTIVITY PROGRAMS AND MOTIVATIONAL INCENTIVES

There are four facets of a public agency's productivity improvement program, according to Holzer and Gabrielan.^b Two of these facets are the social and managerial dimensions. In terms of linkages to motivational incentives, both of these aspects of the program focus on the human element and human potential for achieving productivity.

The social and managerial dimensions of public productivity programs present challenges and offer opportunities to public sector managers. Holzer and Gabrielan^[2] cite two social factors that challenge the managerial capacities of public managers: cultural differences and bureaucratic pathologies. Managers' awareness of employees' cultural differences is likely to affect employee productivity. When managers insist that employees, who are Seventh-Day Adventists, come to work on Saturdays, this is likely to have the opposite effect of improving such employees' productivity. Saturday is their Sabbath Day. Agencies that factor in religious holidays and days of prayer recognize and respect existing cultural differences.

Bureaucratic pathologies are evident when public agencies lack openness to change or accept employees' mediocre performance. Such pathologies stifle productivity. By eliciting, recognizing and using the needs of employees, productivity improvement may occur. When employees feel involved because their views are sought and respected, they are likely to be more committed to their jobs and to improving their

productivity. Motivational incentives that include work-force planning, the training and development of employees, and effective utilization of their skills and talents may also contribute to productivity improvement.

Providing employees with feedback through an effective performance appraisal system also results in productivity improvement. Positive feedback has tended to reinforce and improve performance. Exposure of employees to training and development programs serves to improve weak aspects of their performance, to enhance productivity, and is an integral part of an effective performance appraisal system.

The managerial dimension of the productivity improvement program focuses on the public manager's challenging task of implementing comprehensive public management strategies. Appropriate management strategies provide intrinsic rewards: employee recognition, partnerships, and opportunities for employees to achieve.

The managerial dimension also entails opportunities for cooperative partnerships, and for improving employees' competencies and problems of procedural rigidity. In terms of opportunities, Total quality management (TQM) is advocated. This typifies comprehensive public management that focuses on the potential of the human element to achieve productivity, provides non-monetary incentives, and leads to improved productivity. According to Holzer and Gabrielan,^c TQM involves using "theory-based improvement strategies that allow managers to improve capacity." Cohen and Brand^[4] (in Holzer and Gabrielan)^[3] further elaborated on each aspect of this management strategy:

Total = Search for quality in every aspect of work
 Quality = Meeting and exceeding customer expectations
 Management = Developing and maintaining organizational capacity

By embracing this strategy, agency managers demonstrate their awareness that individuals are encouraged and stimulated to perform when the agency

^bHolzer and Gabrielan have developed a framework for analyzing factors likely to affect public productivity improvement programs: The four facets of the framework are managerial, social, technological and informational factors.

^cSee Cohen and Brand Ref. [3].

Table 2 Non-monetary incentives

	Incentives
Individual	Flexible work schedule, elder care and child care facilities, physical fitness facilities
Job related	Recognition: awards, job enrichment, job rotation
Job environment related	Safe, healthy, attractive, and comfortable work environment
Management/supervision	Management values that are humanistic; management strategies that encourage employee involvement and empowerment, “teaming,” employee training, development and competence
External environment	Respect for cultural differences—public agency makes allowances for prayer days, religious holidays; addresses cultural differences with sensitivity and awareness

shows concern for the quality of the product and for the competencies of the employees who deliver the product.

Procedural rigidity may limit employees' abilities to be innovative. Rigidity *straightjackets* the skilled and talented employee who thrives on improving outcomes. Giving this employee room to be creative is likely to improve productivity.

The meaning and purpose of work are changing. Increasingly, employees are attempting to balance their work lives and their personal lives. Many employees believe that money is not all. Some employees are concerned with finding work that gives them the flexibility to manage their private and professional lives: work that both gives them satisfaction and allows them to spend time with their families. Connie Glaser and Barbara Smalley^d in their book, *When Money Isn't Enough: How Women are Finding the Soul of Success*, examined the phenomenon of individuals in the workplace “who are struggling to find meaning, balance and purpose” in their lives and the choices that they make. Individuals, and this apparently is not limited to women, are finding that they need more quality time with their family: their children, their parents, or elder relatives for whom they care. Employees are factoring these needs into their work expectations. Consequently, the provision of on-site child and elder care facilities are non-monetary incentives that are valued by these individuals. Employees' health concerns or expectations to have time for physical exercise as part of a daily regimen to maintain their health are sometimes factored into their totality of needs. Public agencies that provide health screenings and gyms are providing non-monetary incentives that are likely to improve productivity. Employees' wide-ranging needs and expectations, as well as possible sources of these needs, are summarized in Fig. 1 and in Tables 1 and 2.

REWARDING EMPLOYEES: IMPROVING PRODUCTIVITY SUCCESS STORIES

The humanistic philosophy focuses on the behavioral aspects of the work lives of employees. It focuses on the fact that employees have complex needs and are encouraged by incentives and stimuli other than money. Innovative public management strategies may enhance public managers' chances of improving productivity. According to Halachmi,^e strategic management is required for productivity improvement. Most progressive public organizations have adopted enlightened human resource management practices, rejecting authoritarian, bureaucratic style. Many public managers recognize that their management approaches have to be more flexible and accommodating because individuals have varying concerns. These managers are also aware that they need to be concerned with the social and psychological needs of their agency's workforce; enlightened human resource management practices are important for productivity.

Rose Ann Roberts^[7] documented numerous non-monetary approaches to productivity enhancement in the workplace and provided examples of the successful application of some of these approaches. She argued that, before introducing these approaches, agencies need to review their external environment and undertake systems or departmental analyses to determine forces that affect agency productivity. She advocated productivity enhancement approaches that include the introduction of organizational ombudsmen, quality circles, job descriptions updates and redesign, job teams, job rotation and team building, flexible job time, employee merit/recognition systems, employee education programs, and child care and elder care. Many of these approaches have been successfully used in the private sector. The public sector has also

^dSee Ref. [5].

^eHalachmi conceptualizes strategic management as a requirement for successful productivity improvement. Strategic management is not a panacea and offers no guarantees, according to him. For detailed discussion readers may refer to Ref. [6].

benefited from employing certain non-monetary incentives. According to Roberts, since 1989, some federal offices across the United States have opened on-site child care centers. In the private sector, these facilities also exist. Where the actual facilities do not exist, some organizations provide assistance with child care expenses, referral services, and counseling. Organizations have successfully used job rotation to improve productivity: At Tektronix Graphics Workstation Division, “jobs were rotated so that everyone became a coordinator for a week.” Roberts also described the case of the 1974 Union National Bank of Little Rock as an example of the value of employee merit/recognition systems: This case involved rewarding workers who increased their individual productivity by congratulating the highest producer on a regular basis. In the case of the bank, performance increased 200% in 6 weeks.

Other cases have also been documented elsewhere. An on-line government study, “HRM Policies and Practices in Title 5-Exempt Organizations (1998),” outlined the use of non-monetary incentives that include the following: transportation subsidies, health screenings, leave banks, leave transfers, access to fitness centers, and child and elder care information or facilities. Employees’ concerns to maintain their health, to be on time, and/or to be close to their young children or the elder family members for whom they care are “live” issues.

Motivating and rewarding public employees requires constant attention to employees’ needs and expectations from the time that the employees enter an agency until employees leave. Human resource

management practices that integrate responsive and innovative strategies may be critical for satisfying these needs and for improving productivity.

Non-Profit Organizations, External Relations in

Mordecai Lee

*Department of Governmental Affairs, University of Wisconsin-Milwaukee,
Milwaukee, Wisconsin, U.S.A.*

INTRODUCTION

A focus on external relations in non-profit organizations assists in understanding that an agency consists of more than the sum of its tangible components, such as employees, finances, and real property. Similarly, the skill sets needed by a non-profit executive extend beyond managing these “in house” components, such as human resources, budgeting, and asset management. An external relations perspective helps emphasize that the totality of a non-profit agency includes people and entities that are outside its formal and legal boundaries, and the duties of a non-profit executive include leading “beyond the walls,” such as through management of external relations.

INCREASING IMPORTANCE

Several recent trends have contributed to the increasing importance of external relations in non-profit organizations. First, the emergence of instant communications technologies permits and facilitates new forms of external communication that previously were cumbersome or expensive. For example, an Internet newsletter to contributors has many financial and temporal advantages over a hard-copy version that is mailed to a constantly changing mailing list.

Second, in an era of increasing privatization, subcontracting, third-party service delivery, alliances, public-private partnerships, and social entrepreneurship, more of the totality of a non-profit agency is outside its formal boundaries of, for example, activities that its salaried employees engage in.

Third, one manifestation of external relations, advocacy, is becoming an increasingly visible activity in the non-profit sector. Non-profit organizations with a primary mission of public advocacy are a fast-growing category within the non-profit sector. Salamon estimated that the number of non-profit civic organizations grew 68% between 1977 and 1992, increased their employment by 48%, and through 1995, increased their revenue by 216%.^[1] For other categories of non-profit agencies, advocacy is an important secondary activity. For example, a 1996 conference on the contemporary role of foundations identified their

increased “need for professional communication capabilities to educate their publics and influence policy debates.”^[2]

Fourth, the Guidelines for Graduate Professional Education in Non-profit Organizations, Management and Leadership issued by the National Association of Schools of Public Affairs and Administration (NAS-PAA) include external relations as one of 14 subjects that should be included in a curriculum.^[3] Similarly, Wish and Mirabella listed public relations—within the larger rubric of “fundraising, marketing and public relations”—as one of the seven major categories of a curricular model of non-profit management education.^[4] A survey of faculty, practitioners, and students regarding the skills needed by non-profit administrators listed public relations as one of eight “most important” core subjects.^[5]

Fifth, management theorists have increasingly emphasized the importance of external relations. It is a specialized staff function within large organizations as well as an operating concept shared by the agency’s management. The higher managers move up the hierarchy, the more they deal with external issues and constituencies. This necessitates a greater need for having and using public relations skills. In the private sector, corporate CEOs are now estimated to spend 25 to 75% of their time on external relations.^[6–9]

SCOPE

There is a lack of uniformity of nomenclature for this subject matter. External relations, as an overarching moniker, is sometimes also called public affairs, public relations, external communication, community relations, or governmental affairs.^[10] The critical decision point is what external relations encompasses. A literal definition of external relations would encompass all interactions between the salaried employees of a non-profit agency or its board members with any other individuals or organizations. This, however, would include activities that are the core mission of a non-profit agency, such as the marketing and delivery of its services to clients or its relationships with donors and volunteers. It would also cover business activities, such as purchasing and vendor relations. These latter

activities are generally ministerial in nature from the perspective of external communications strategies. When external relations is defined to cover the totality of the agency's out-of-house contacts, it then loses any analytic or applied utility. Focusing on everything is tantamount to highlighting nothing.

Similarly, a broad approach to external relations, as defined by the NASPAA guidelines, would include all advocacy organizations. However, for these non-profit agencies, external relations is their *raison d'être*.^a The study of their external relations would be tantamount to a review of the entire agency's operations. In this situation, too, the prism of external relations adds little to the observer or practitioner.

A pragmatic approach to external relations focuses on those discrete activities that are important to the life of a non-profit agency but are ancillary to the agency's central mission and purpose as well as its ministerial external business relationships. External relations covers secondary activities of an agency that are important to its overall mission but are neither its central nor primary purpose. It contributes to broad, amorphous goodwill toward the agency on behalf of the public at large and other more selected populations.

External relations is defined here as an agency's secondary out-of-house activities, whether planned or unplanned, that affect its standing with the public at large and with specific groups, exclusive of its ongoing external relationships with clients, volunteers, and funders. Specifically, external relations includes media relations, lobbying and advocacy, citizen relations, community relations, and crisis management. An effective external relations operation must be fully integrated into the primary mission of the agency, by working to further the agency's strategic plan, as well as its marketing, development, volunteer, and employee training programs. For more information on conducting all aspects of external relations, see Refs.^[12,13].

MEDIA RELATIONS

The most common purpose of non-profit external relations is to deal with reporters from the news media. This can be reactive or proactive. As a reactive activity, agency staff handle inquiries initiated by journalists covering a story that has some connection to the agency, such as its programs, financing, operating policies, or expertise. When answering media inquiries, two approaches are possible for larger agencies with specialized media relations staff. Some agencies prefer to rely on their expert staff to deal directly with the media.

This is a way to protect less expert employees of the agency from common mistakes when talking with a reporter. Using this approach, the spokesperson for the agency is the media relations professional. Other agencies use the media relations staff as facilitators. With this latter approach, staff focus on connecting the reporter to the optimal agency employee for that particular issue. In these situations, instead of having one person as the agency's permanent "face" and "voice," the agency has multiple spokespersons.

With proactive media relations, a non-profit agency initiates an interaction with the media, in an effort to persuade reporters or editors that a specific story idea is worth covering. In these cases, the reason for contacting the reporter is usually structured around an upcoming agency event, such as an unveiling of a new program, the announcement of a major contribution or the laying of a cornerstone of a new facility. These events are planned and intended to make the agency look good. Coverage is unpredictable and often dictated by the press or absence of other "breaking news" in the same news cycle as the agency event.

The scope of an agency's media relations activities should not be limited to the traditional mass media of daily newspapers, commercial television stations with news departments, and commercial radio stations with news departments. In addition, non-traditional mass media can be a further means for the agency to promote its message. The latter can include weekly newspapers, shoppers, public television and radio, student newspapers, radio stations, regional magazines, organizational newsletters, and specialized publications intended for such groups as businesses, women, residents of a particular neighborhood, or hobbyists.

Sometimes, a non-profit agency needs to bypass the media so that the public at large or a specific audience hears the agency's message despite a lack of coverage by the traditional mass media. In that case, communication activities fall under the rubric of citizen relations, rather than media relations (see below). For more information on conducting media relations, see Refs.^[14-16].

LOBBYING AND ADVOCACY

This area consists of two separate but related activities. First, lobbying (sometimes called government relations) describes the direct efforts by a non-profit agency to affect public sector decision making. This can occur at the local, state, or federal level and can be targeted toward the legislative branch, the chief elected official of the executive branch (mayor, county executive, governor, or president), or to a government agency. This form of lobbying focuses on issues, not

^aAn example of an advocacy organization is a Jewish community relations council. See Ref.^[11].

direct funding of the agency's programs. Hence, lobbying by the American Heart Association of Congress and the president for increased federal funding for heart research would be considered part of the agency's external relations activity. On the other hand, lobbying by the association of a specific federal agency for grants and contracts to fund the association's direct services would generally not be considered external relations.

The difference between the two examples is that the former reflects the disinterested views of the organization, while the latter concerns its self-interest. This distinction is the effect of the definition of external relations used here, namely, that it is not about the core mission and in-house operations of an agency, such as its ongoing relationships with clients, volunteers, and funders. This latter activity involved in government funding is sometimes called program funding, grantsmanship, or contract management. In addition, as mentioned earlier, this overview of external relations is not applicable to non-profit agencies whose main purpose is issue advocacy.

The second activity by a non-profit agency under this rubric is usually called grassroots advocacy. This is different from lobbying, because its focus is on efforts by the organization to affect public-sector decision making indirectly. A non-profit agency sometimes tries to mobilize its existing networks of volunteers, donors, and other supporters to express their opinions to a particular government official, agency, or institution. Grassroots advocacy activities can also be aimed at the public at large, trying to mobilize any citizen to voice the agency's views to a particular government agency or person.

Grassroots advocacy is sometimes contrasted to "astro-turf" advocacy. The latter describes efforts by for-profit businesses to mobilize public opinion through misleading appeals, front organizations that hide their true identity, efforts that are geographically pinpointed to influence the views of a small number of key elected officials, and the use of advanced technology to forward the calls of individuals from the front-organization's 800 telephone number directly to, for instance, the Washington office of their representative in Congress. For more information on conducting lobbying and advocacy, see Refs.^[17-19]

CITIZEN RELATIONS

A non-profit organization interacts with many selected publics, often identified by their relationship with the agency, such as clients, volunteers, donors, government agencies, and the media. Sometimes it interacts with groups identified by socioeconomic or ethnic status

(such as low income or Hmong), by geography (residents of southern Smith County), or by affinity (animal lovers or HIV positive). Yet, a non-profit agency also interacts with the broad and undifferentiated public at large. The phrase "public relations," in its literal meaning, conveys this activity. However, that specific phrase has evolved to represent a different and generally negative meaning. Nonetheless, in its original meaning, the phrase is helpful, because it identifies a distinct population group that a non-profit agency interacts with, namely, the citizenry as a whole. To avoid misinterpretation, another title for this activity is "citizen relations."

Akin to government agencies and commercial products, a non-profit agency has an image. This is a broadly held set of perceptions about the organization by public opinion as a whole, rather than by a small select group within the general population. For example, a non-profit might be viewed as "classy," "in trouble," "successful," "elitist," "caring," etc. These images evolve slowly (and change slowly) based on the invisible civic network that aggregates individual opinions held by the public at large. Non-profit agencies need to pay deliberate attention to the large and small details that contribute positively or negatively to its public image.

In that respect, citizen relations is brand management. An agency can design its casual interactions with the public along with its formal relations with its specialized publics (clients, volunteers, supporters) to create a consistent image. These can include such details as its name, logo, graphic look, signage, web page, public service announcements, media coverage, etc.

Citizen relations is not involved with the core mission of an agency, such as its customer services and fundraising. Rather, citizen relations is aimed to build goodwill toward the agency with the public at large. It enhances the image of the agency in civil society.

In public administration, citizen relations has a direct impact on the future of an agency. For example, the "favorability" ratings of federal agencies can be measured.^[20] A NASA astronaut, indoctrinated in the agency's sensitivity to public relations, stated bluntly that "public opinion helped determine funding."^[21] An official of a state agency observed that "name recognition is important in gaining support from the state Legislature."^[22] Elected officials want to be viewed as supporting popular agencies and criticizing those with low favorability ratings. This connection between image and funding, while more amorphous, also occurs in the non-profit sector. Agencies that have favorable images with public opinion are more likely to be successful, whether in fundraising, expansion, new programming, or political support. Through a well-planned and comprehensive approach

to citizen relations, agencies can gradually improve their public standing and, therefore, enhance their success.

COMMUNITY RELATIONS

A separate external relations activity is community relations. It is regrettable that the word "community" has become so overused in contemporary times that it has lost most of its previous substantive meaning. Nonetheless, as an organizing concept, it can be helpful in focusing attention on two distinct aspects of a non-profit agency's external relations.

First, community relations refers to populations living in close physical proximity to any of the agency's facilities. By their nature, the locations of a non-profit agency's buildings can create problems and even opposition to their existence. That is why a non-profit agency benefits by directing deliberate attention to the populations in the neighborhoods in which it is located. This might include ongoing neighborhood liaison, frequent contact, a hotline for reporting problems, open houses, advisory committees, and regular newsletters. Given the predominance of the NIMBY syndrome ("not in my back yard") in contemporary times, agencies are well advised to deal proactively with potential neighborhood problems. For example, before any public announcement about plans for a group home, an agency would do well to work intensively with the residents near the site to alleviate the automatic fears these proposals normally provoke.

Second, community relations refers to concentrated relationship building with a particular and identifiable segment of the population that would have a discernable interest in something the agency is doing or planning to do. These are not publics with which an agency routinely interacts for client service, volunteer recruitment, or donor development. Rather, there may be racial or ethnic groups that have a discernable but indirect sensitivity to the agency's activities.

For example, a housing redevelopment agency might have selected a specific neighborhood for its efforts. Certainly, current residents of the neighborhood might have concerns about gentrification pushing up property values to the point that they could not afford to continue living there. That would require the first category of community relations activities. However, there may be other population groups that are not directly affected, but are traditionally concerned about such issues, such as the city-wide African American population, the city-wide Hispanic population, etc. In this example, effective community relations would call for initiating contacts with these demographic groups, although they are not affected, as a whole, by the project in question.

CRISIS MANAGEMENT

All crises have external relations implications, because that is when an agency gets the most attention from the media, government, and the public. Sometimes an emergency is isolated to the agency, such as a major physical disaster at one of its facilities, for instance a fire, or the release of an extremely negative public report, such as an audit or newspaper expose. At other times, the emergency is community-wide and the agency is playing a major remediating role, for example in response to a public health epidemic, a major disaster such as a transportation-related accident, etc.

In all cases, the agency not only needs to respond substantively to the crisis but also have a mechanism to smoothly handle the sudden increased public attention. The guiding principle for these situations is the advertising tag line that "one never has a second chance to make a first impression." This requires significant advance planning, both managerial and logistical, as well as a close integration of senior external relations staff with the agency's decision-making group. For more information on conducting the external relations aspects of crisis management, see Refs.^[23-25].

Nuremberg Trials and Charter

Morton J. Tenzer

*Department of Political Science, University of Connecticut,
Storrs, Connecticut, U.S.A.*

INTRODUCTION

The Nuremberg Trials of major Nazi war criminals, properly the International Military Tribunal, were conducted from October 1945 to October 1946. Twenty-four of the leading figures of the Nazi regime were accused before a tribunal of judges from Great Britain, the United States, the USSR, and the provisional government of France under the authority of the Charter established by the four powers on August 8, 1945. One of the defendants was excused for age and health reasons, one committed suicide during the trial, three were found not guilty, 11 were sentenced to death, and the rest were sentenced to various terms from 10 years to life imprisonment.

The trial served many purposes. It publicized fully to the world for the first time the full range of monstrous activities of the Nazi regime, including the extermination of virtually the entire Jewish population of Central Europe and the slaughter of millions of other civilian victims deported for forced labor or deliberately killed for belonging to other categories of humanity, such as Gypsies, gays, political activists, and dissenters of various sorts. The trial established some important precedents: that such enormous crimes could be subjected to a fair and orderly judicial process; that no one, even a head of state, was immune from such judgement; and that conspiring to commit an aggressive war and crimes against humanity were subject equally to such judgement along with more traditional crimes against the laws of war. A fundamental principle was reinforced—that obedience to superiors' orders did not excuse or justify behavior of subordinates who comply with illegal orders. As a result of a subsequent trial at Nuremberg of Nazi doctors who performed hideous experiments on concentration camp prisoners, the Nuremberg Code was adopted to provide guidelines for research on human subjects, now part of the law in the United States. While the trial and punishment of the Nazi leaders did not deter wars from occurring in the subsequent half century, they had a profound effect on the regulations and behavior of public officials whose previous immunities had been stripped by the Nuremberg Charter^[1] and trials.

NUREMBERG CHARTER

At the end of World War I, Kaiser Wilhelm had been allowed to flee unharmed to settle in the Netherlands. No formal culpability for that war was ever established, and various controversies and myths developed about the origins of that war and its conclusion, which contributed to the rise of the Nazi party and its theory of a “stab in the back” that allegedly led to Germany's defeat. The victors over Napoleon in the last general European war a century before 1914 dealt with him summarily, exiling him first to Elba and then to St. Helena without any formal process. As the war in Europe drew to an end in 1945, it was apparent to the Allied leaders that Nazi Germany, in the course of the war, had committed crimes of such unparalleled gravity and extent that its leaders must be punished for their complicity in these crimes. President Roosevelt had warned of such accountability as early as 1942. Churchill wanted Adolph Hitler, the Nazi leader, and his associates shot summarily, but the United States and the Soviet Union favored holding trials, although they had vastly different concepts about how to conduct legal proceedings. There was some fear that Hitler might use his frenzied rhetorical abilities to disrupt a trial. When the war ended in May, 1945, Hitler and two of his closest associates, Joseph Goebbles, the chief Nazi propagandist, and Heinrich Himmler, the head of the SS and secret police, had committed suicide, and Martin Bormann, Hitler's top aide, was missing, although also presumed dead. Benito Mussolini, the Italian Fascist dictator, was also already dead. Of the top Nazis, only Hermann Goering, the regime's number two man, was captured alive. The Allies quickly decided to try Goering and other high-level Nazi officials, and on August 8, 1945, the four victorious powers (Great Britain, the United States, the USSR, and the provisional government of France) adopted the Charter of the International Military Tribunal empowered to conduct trials of Nazi war criminals.^[2]

The Tribunal would consist of four judges, each with an alternate representing the four signatories. Its jurisdiction included the power to try and punish major war criminals of the European Axis powers for crimes defined as follows: Crimes Against Peace, which

meant planning, organizing, or waging a war of aggression; War Crimes, the violation of the laws or customs of war, such as the murder of prisoners of war, deportation of civilians to slave labor, and devastation not justified by military necessity; and Crimes Against Humanity, the murder, extermination, enslavement, and deportation of civilian populations or persecutions on political, racial, or religious grounds. Additionally, the Charter stated that the official position of defendants, whether heads of state or other high rank, would not free them from responsibility for their actions, and the fact that defendants acted on orders of their government or a superior would not free them from responsibility.

Each signatory to the Charter was to appoint a Chief Prosecutor, and the prosecutors acting as a committee were to draw up an Indictment with full particulars specifying charges against the defendants and to collect all necessary evidence for presentation to the Tribunal. The American Chief Prosecutor, appointed by President Truman, was Justice Robert Jackson, on leave from the Supreme Court of the United States. He became chairman of the prosecutors' committee and bore the main burden of prosecutorial activities. The United States had by far the largest staff and played the major role in the collection of evidence, interrogation of prisoners, the running of the prison where the defendants were incarcerated, and the staffing of the courtroom.

The Charter also provided for a fair trial for the defendants by assuring an indictment with detailed particulars of the charges against each defendant, and by providing the defendants with the right to counsel, to present evidence supporting their cases, and to cross-examine witnesses for the prosecution. All documents were to be translated into the defendants' language. The Tribunal was given the power to summon witnesses and documents, and to impose punishment including death upon conviction of any defendant. It was required to explain the reasons for guilt or innocence of each defendant, and its proceedings were to be conducted in English, French, and Russian, as well as German. The permanent seat of the Tribunal was Berlin as the Russians wanted, but the trial and subsequent trials were held in Nuremberg, where the Americans had facilities and staff adequate for the purpose.

INTERROGATIONS

Even before the Charter, interrogations of the Nazi prisoners had begun.^[3] Practical difficulties included the shortage of able translators, the complexities of duplicating transcripts in many languages, the dispersion of the prisoners before they were brought to

Nuremberg, and the resistance of the prisoners to admitting guilt. The major difficulty, however, was the interrogators' lack of knowledge and understanding of the organization and mechanisms of the totalitarian Nazi regime. The prosecution was learning about the system as they were proceeding to draw up the indictments, and the early notions of a simple, tightly run dictatorial structure gave way to an understanding, perhaps never fully achieved, of the multiple layers of authority, duplicative agencies, and unclear lines of responsibility that characterized the Nazi system. It was difficult to coordinate the information received from hundreds of other prisoners, victim witnesses, and the voluminous documents that had fallen into Allied hands and required translation and incorporation in the prosecution's case.

Aside from Goering, Rudolph Hess (Hitler's longtime Nazi party associate) and Joachim Von Ribbentrop (the Reich Minister of Foreign Affairs) and a few others, it was not clear who should be tried as a major war criminal. Preparing the case was a logistic nightmare, made more difficult by uncertainty about the nature of the charges and the identity of the defendants. Work which should have taken months, if not years, had to be compressed into weeks, because the Allied Powers were determined that the trial be held as quickly as possible in the autumn of 1945.

INDICTMENT

After considerable debate among the Allied prosecutors concerning the identification of the defendants who were to be charged as major Nazi war criminals and the nature of the accusations against them, the prosecutors, working under severe time constraints, presented the indictment to the Tribunal on October 19, 1945, in Berlin. The trial was scheduled to begin on November 20 in Nuremberg, allowing the defendants a month to secure counsel and prepare their defense.^[4]

The indictment was innovative in at least two respects. First, following Anglo-American common law tradition, the defendants were accused in the first count of the indictment of being guilty of a *conspiracy* to commit the crimes against peace, war crimes, and crimes against humanity specified in the Charter. Second, several major organizations were indicted for their roles in the crimes of the individual defendants and were to be declared criminal organizations if found guilty. Membership in these organizations would create a presumption of guilt for defendants in future trials. These groups were the Reich Cabinet, the leadership corps of the Nazi Party, and police, security, and military staff units. While many of the defendants had multiple roles—Goering was a party leader, a cabinet

member, head of the four-year plan for economic development, a general in the SS, and Commander-in-Chief of the Air Force—they represented different elements of the Nazi power structure. Some were primarily party leaders, and others had been foreign policy leaders. Several had operated under Himmler in the persecutions and exploitation of slave labor and in the extermination program. Others had key roles in the German economic war effort and represented German business and finance involved in Nazi activities. Four were military officers of the high command, and others had held scattered positions in the government. There were 21 defendants who attended the whole trial and testified in their own cause. The indictment spelled out in great detail a gruesome account of the depredations the Nazi regime had committed in Europe. It referenced treaties broken, wars launched, numbers of transports and deportees from various countries, cities and towns destroyed, looted and expropriated property, and millions of Jews exterminated, as well as millions of others worked and starved to death.

THE TRIAL

Between November 20, 1945, and August 31, 1946, there were 403 open sessions of the Tribunal.^[5] Testifying for the prosecution were 33 witnesses and 61 for the defense, in addition to the defendants. Thousands of documents and affidavits were received, nearly overwhelming the ability of the staff to translate and collate all of the material.

The evidence against most of the defendants was overwhelming, as the prosecution presented through documentation and witnesses the details of the barbarities committed by the Nazi regime from its inception. Some unusual pieces of evidence were used. A specially produced four-hour film, *The Nazi Plan*, was shown on December 11. Tattooed human skin tanned at the Buchenwald concentration camp and a shrunken head of a Polish youth from Auschwitz were displayed along with photographs, charts, and tables illustrating elements of the prosecution's case.^[6] Perhaps the two most extraordinary witnesses were Dieter Wisliceny, one of Adolph Eichmann's assistants who testified about the transport of millions of victims to the camps, and Rudolph Hoess, the commandant of Auschwitz who admitted supervising the gassing of two million persons between the summer of 1941 and the end of 1943. Wisliceny said that Eichmann, who had operational responsibility for the extermination of the Jews, had shown him a written order from Himmler asserting this was the Fuhrer's (Hitler's) decision.^[7]

The visual and verbal evidence of the crimes of their regime shook the defendants. All present had pleaded not guilty. Goering, as in his interrogations, remained

the most arrogant and unapologetic. Most of the others tended to deny their own responsibility for the crimes and claimed that they did not know what the others had done. The military men were more willing to acknowledge responsibility, but they denied knowledge of atrocities, and haggled over details. Continued admiration, if not adulation, for Adolph Hitler was expressed by almost all the defendants who claimed only to be following his lead, inspiration, and orders. The denials of guilt were palpably false and the refusals to accept responsibility a strategy to avoid conviction and a possible death penalty.

The defense raised an important moral issue: what was the responsibility of men who served an evil government which punished dissent with violent ruthlessness? Can all the blame be shifted to the top? Does obedience to superiors excuse complicity? If one is resigned to events, detached emotionally from actions, is this acquiescence in a criminal sense? The generals and admirals were ready to assume responsibility for their actions but not for crimes committed under their command. At most, they would admit to having made mistakes. Von Ribbentrop agreed to political responsibility but not criminal responsibility, and others insisted on their innocence and claimed to have opposed many of the Nazi initiatives.

JUDGEMENT

The Tribunal rendered its judgement^[8] on September 30 and October 1, 1946. Of the organizations, the Reich Cabinet, the General Staff and High Command, and the SA were acquitted. Twelve defendants were sentenced to death by hanging. Three were sentenced to life imprisonment and four others to various lesser terms of imprisonment. Three defendants were acquitted. Arriving at these decisions had not been without controversy among members of the Tribunal, and the Soviet member formally dissented from the three acquittals and the life sentence of Hess, whom he believed deserved the death penalty. He also dissented from the decisions about the Reich Cabinet and the General Staff and High Command, which he thought should be declared criminal organizations along with the leadership corps of the Nazi party, the SS, the SD, and the Gestapo.

SIGNIFICANCE

The Nuremberg Trials had widespread ramifications. Although they have been criticized as "victor's justice," they established important precedents that bear on the behavior of states in international politics, and on individuals, especially government officials throughout the world. The Trial demonstrated that a judicial process

could be conducted to hold government officials, even heads of state, responsible for criminal actions taken leading to war and during war. Aggressive war, defined at Nuremberg, was construed as a crime violative of treaties going back to the Hague Conventions at the turn of the twentieth century. Activities undertaken even in the stress of war under direct orders of superiors can be construed as war crimes and crimes against humanity. Obeying orders is an excuse but in no way a justification for inhumane behavior.

Nuremberg Code

Subsequent proceedings held at Nuremberg tried over a hundred lower-level Nazi officials. Of these, the most significant was the Doctors Trial, in which a number of German doctors who had performed medical experiments on concentration camp inmates were put on trial. The almost unimaginably cruel nature of these sadistic experiments, whose subjects almost invariably died or were killed after their tortures, led the judges at the trial to include in their verdict a section called “Permissible Medical Experiments,” which became known as the “Nuremberg Code.”^[9] The Code became a landmark document in medical ethics and has become parts of the law and regulations of research on human subjects in the United States and elsewhere. That voluntary consent of the human subject is absolutely essential, the first point of the Code, has become the basis of all human subjects research, even in the social sciences. Other points in the Nuremberg Code bar research that causes unnecessary physical and mental pain or injury and forbids research when it is reasonable to expect death or disabling injury will result.

Nuremberg Principles

In 1946, the new General Assembly of the United Nations approved the Nuremberg Charter and appointed an International Law Commission to formulate principles derived from the Trial. It was not until 1950 that the General Assembly received the Commission’s report and adopted the seven so-called “Nuremberg Principles,” which basically restated much of the Charter and Indictment with regard to crimes against peace, war crimes, and crimes against humanity. The principles include the vulnerability of heads of state and government officials to the application of international law; that action under orders does not relieve responsibility for criminal acts; that accused have the right to a fair trial; and that complicity in crimes against humanity is punishable by law.^[10]

In 1948, the United Nations had adopted the Universal Declaration of Human Rights which

stemmed in part from the findings of the Nuremberg Trials. Article 3 states the right of everyone to “life, liberty and security of person.” Article 5 states “no one should be subject to torture or to cruel, inhuman or degrading treatment or punishment.”^[11] Also in 1948, the Convention on the Prevention and Punishment of the Crime of Genocide was signed in Geneva, providing a more definite legal basis for action against what was called the “odious scourge” of genocide, defined as “acts committed with the intent to destroy in whole or part, a national, ethnical, racial or religious group, as such.”^[12] The word genocide had not come into common use during the Trial in 1945, but clearly it means much the same as the Crimes against Humanity of the Nuremberg Charter.^[13]

For decades after the Nuremberg Trials, their direct influence on the behavior of states and public officials was minimized by the Cold War. The subsequent trials and de-Nazification program in Germany were prematurely ended. The Gulag system of punishment and labor camps in the Soviet Union, in which millions of people were incarcerated and died, continued unchecked until modified by Nikita Khrushchev in 1953 and was not ended until Mikhail Gorbachev’s rule in the 1980s. The indirect effects of Nuremberg, nevertheless, became widespread throughout western countries and the United States, evidenced by the increased sensitivity of public officials to their treatment of citizens and other inhabitants of their countries. Capital punishment was abolished in Europe over the decades.

In recognition of the responsibility of subordinates to disobey illegal orders of superiors within a government administration, federal- and state-level statutes protecting “whistle blowers” were adopted in the United States. Even the ombudsman movement, creating a position within agencies to mediate disputes between citizens and officials and among administrators, although originating in Sweden, was a reflection of the concerns raised in Nuremberg about the callous indifference of Nazi officials to the rights of the people with whom they dealt. The development of government guidelines for research on human subjects enforced by the United States Department of Health and Human Services, including the creation of Institutional Review Boards at hospitals, universities, and other research centers, was based on the Nuremberg Code.

The direct implementation of the Nuremberg Principles and the Genocide Convention languished for decades. In the 1970s, under the Carter Administration, a renewed emphasis was placed on human rights in American foreign policy. In 1979, the Office of Special Investigations in the Justice Department was created to search for Nazi war criminals who may have entered the United States with false credentials after the war. This office’s work led to 54 deportations, and continued as late as 2002.

When the focus was on the struggle with the Soviet Union, there was little reference or recourse to the Nuremberg Principles or the Genocide Convention, and atrocities occurred from Algeria to Cambodia without significant response by the international community. Some minor criminal prosecutions occurred such as the trial of the officer responsible for the My Lai massacre in Vietnam. The United States, a signatory to the Genocide Convention in 1948, did not ratify it for four decades until 1988.

A major shift in attitudes became evident in the 1990s with the end of the Cold War. In 1998, the former dictator of Chile was arrested in London for crimes committed in Chile under his rule, and the highest court in England held him eligible for trial despite the fact that he had been head of state. The genocidal activities in the former Yugoslavia led to the trial of Serbs and Croats in 2000 for war crimes at The Hague, and the chief defendant was Slobodan Milosovic, the former president of Yugoslavia. War crimes trials were held in Rwanda to punish the perpetrators of the genocide committed by the Hutu inhabitants of that country against the Tutsi minority, and in 2002, Indonesian military leaders went on trial for atrocities committed by their forces in East Timor. At Rome in 1998, a treaty was signed by 120 countries, including the United States, to establish an International Criminal Court that would prosecute individuals for war crimes, genocide, and other gross human rights violations. On April 11, 2002, the United Nations announced that 66 nations had ratified the treaty, bringing the court into existence and replacing the ad hoc system of tribunals that had begun at Nuremberg.^[14] More than 50 years after they were conducted, the Nuremberg Trials had become a vital precedent for the prosecution of government leaders and officials for crimes against peace, war crimes, and crimes against humanity.

CONCLUSION

The Nuremberg Trials of 1945–1946 punished many of the leading figures in Nazi Germany's attempt to

conquer Europe and exterminate entire populations. The trials served as an inspiration for the adoption of international treaties and conventions, UN resolutions, and national laws regulating the functions of public administration and the behavior of public officials. Many decades passed before the power of the Nuremberg Trials as a precedent became evident, but at the turn of the twenty-first century, war crimes trials dealing with events in Europe (Yugoslavia), Africa (Rwanda), and Asia (Indonesia) demonstrated the viability and relevance of Nuremberg again.

Offset Requirements in International Public Procurement

Travis K. Taylor

Department of Accounting, Economics and Finance, Christopher Newport University,
Newport News, Virginia, U.S.A.

INTRODUCTION

Consider the following international transaction between a multinational corporation and the government procurement office of Australia. In an effort to win the bid to sell new aircraft to Australia, an American company made arrangements to provide extra (legal) benefits to the Australian economy. Among the benefits this included the marketing and sale of Australian lollipops from Sweets Ltd to the U.S. navy. This arrangement, which actually took place in the early 1990s, is formally known as an offset contract. Common in both developing and industrialized countries, the offset arrangement is one of the most important innovations in international public procurement policy. This article describes the legal framework of offset contracting and employs the tools of the *new institutional economics* to explain why governments are electing to leave the price margin for some types of purchases.

WHAT IS AN OFFSET?

Offsets are contracts that require the seller to transfer extra economic benefits to the buyer as a condition for the sale of goods and services. In many instances, governments prefer to realize these benefits in the form of in-kind transfer, instead of bargaining for discounts of the sale price.

Although few outside those actually engaged in the practice of offsets are aware of this contractual arrangement, it has become an increasingly popular tool of government procurement. Common in exchanges involving aerospace goods and services, offsets permeate the market for defense systems and weapons. These arrangements also arise when governments purchase telecommunications equipment, computers, and a myriad of other goods that need not embody high technology.

Offsets often appear under the guise of *compensation packages, industrial benefits programs, cooperative agreements, and countertrade policy*. The arrangement, at its most fundamental level, is straightforward: a purchasing government obliges a foreign seller to include extra benefits with the sale of the base good. The foreign firm may then sign individual offset contracts

with local firms in the purchasing government's local economy.^a Aside from this buyer-seller relationship, offsets vary considerably in form. Offset transactions may take, but are not limited to, any of the following forms: subcontracting, technology transfer, countertrade, foreign investment, marketing assistance, training, co-production, and licensed production.^b

One can make a further distinction between direct and indirect offsets. Direct offsets call for work that relates in some fashion to the good purchased by the government. Indirect offsets require the seller to transfer some form of economic benefit to the purchasing country that is unrelated to the purchased good.^c The hierarchical structure of offset design is shown in Fig. 1.

Consider two different government procurement examples. In 2003, the American firm Lockheed Martin announced the sale of 48 F-16 aircraft to Poland for \$6.023 billion. As part of the contract, Lockheed Martin agreed to provide Poland with one of the more lucrative offset packages ever recorded. The company would create—over the course of 10 years—economic benefits (jobs, technology transfer, and so forth) in Poland worth \$9 billion.^[1] The basic offset arrangement is depicted in Fig. 2.

An example of a civil offset arrangement involves AT&T's successful expansion into the Middle East. To win the bid to supply a telecommunications infrastructure for Saudi Arabia, AT&T included offsets in 1994. AT&T agreed to provide billions of dollars in new work and technology transfer for the Saudi economy.^[2] By 1998, AT&T had fulfilled most of its obligations by teaming with local Saudi businesses to form equal equity joint ventures. The joint ventures are now successfully supplying production inputs to AT&T (and spin-off Lucent Technologies) and other export markets.

We call offsets non-standard contracts because they require *conditionality* and *additionality*.

^aThe contracts may or may not designate specific local firms with whom the foreign seller will work, depending on the particular offset agreement. Contractual design varies considerably because offsets can accomplish multiple objectives.

^bCountertrade includes barter, buyback, and counterpurchase transactions.

^cIn offset language, researchers and practitioners usually refer to the purchased good as the "base good" or "base exchange."

Fig. 1 Hierarchical design of offset policy by a purchasing government.

Conditionality means that the buyer will only purchase from the seller if the seller provides economic benefits to the buyer. This is, effectively, a reciprocal exchange condition. Offsets also require the seller to demonstrate that the new business transferred to the buyer's country would otherwise not occur. This is the additionality requirement. Competition with offsets involves price-quality-content trade-offs, thereby adding another dimension to the price-quality margin of most markets.

Although Organization for Economic Cooperation and Development (OECD) international trade statistics do not officially track offsets and other compensation agreements, studies show that the market is sizeable. For example, estimates of countertrade as a percentage of world trade range from a conservative 8% to a high of 20%.^[3] Countertrade that is a result of government procurement requirements qualifies as offset, whereas an agreement between two private firms does not. Most aerospace and defense goods sold to foreign governments include offsets ranging from approximately 10% to 150% of the sale price. In the U.S. defense industry alone, 42 U.S. companies signed 513 new offset arrangements between 1993 and 2004 valued at \$55.1 billion.^[4] These data indicate that offsets accompanied the sale of 173 U.S. defense products during the period (Table 1). The actual number of offset contracts is far greater than 173 because the seller typically agrees to provide offset work to numerous firms in the purchasing government's economy.

Moreover, offset contracts are increasing in use. The number of non-Soviet bloc governments officially using industrial cooperation and compensation policy increased from 17 to 78 between 1964 and 1986.^{[5]d}

^dIt has long been recognized that Soviet bloc countries engaged in various forms of offset and countertrade policy during the post-World War II years. Their experience is reviewed in the historical development of offsets chapter in Taylor (2001). (Taylor, T.K. 2001. Ph.D. Dissertation. University of Connecticut.)

Fig. 2 Simplified offset arrangement.

Wood reported that approximately 130 countries maintain offset offices or agencies with their respective governments.^[6] Yet, for a policy instrument of such apparent importance, there is a dearth of comprehensive examinations.

LEGAL FRAMEWORK

The offset is an extra sweetener—some form of economic activity beyond the base exchange—that governments require or encourage when accepting bids for procurement orders. *Defense* offsets arise when a government purchases military goods from a foreign seller. If the government requires offsets for the procurement of non-defense goods, it is known as a *civil* offset program. Although not the norm, civil offsets are gaining popularity despite their illegality under World Trade Organization (WTO) laws.^c Article XVI of the WTO's Fair Trade Practices prohibits offsets not associated with military purchases. Governments use several strategies to circumvent this article.

Article XVI is virtually impossible to uphold. Offset is one of the more nebulous policy instruments in government. In fact, many procurement requirements never mention the word "offset," preferring the more innocuous and vague "compensation packages," "cooperative agreements," and "industrial development." Another technique is for the purchasing

^cThe data show that approximately 10–20% of the offsets originate from governmental purchases of civil goods and services.

Table 1 Summary of U.S. defense offset arrangements, 1993–2004 (\$ millions)

Year	U.S. companies	Agreements	Base export value ^a (\$)	Offset value (\$)	Offset ratio ^b %	Countries
1993	17	28	13,935	4,784.4	34.3	16
1994	18	49	4,792.4	2,048.7	42.7	20
1995	20	47	7,529.9	6,102.6	81.0	18
1996	16	53	3,119.7	2,431.6	77.9	19
1997	15	60	5,925.5	3,825.5	64.6	20
1998	12	41	3,029.2	1,768.2	58.4	17
1999	10	45	5,656.6	3,456.9	61.1	11
2000	10	43	6,576.2	5,704.8	86.7	16
2001	11	34	7,017.3	5,460.9	77.8	13
2002	12	41	7,406.2	6,094.8	82.3	17
2003	11	32	7,293.1	9,110.4	124.9	13
2004	14	40	4,927.5	4,329.7	87.9	18
12 year total	42	513	77,208.6	55,118.5	71.4	41

^aBase export value is the summation of U.S. sales to countries who require offsets

^bOffset ratio % is the compensation ratio defined as the (offset value/base export value) (From page 33 of Ref.^[4].)

government to consider, although not require, offsets with bids. In other words, the government does not mandate offsets, but it is highly recommended. In some cases, procurement officials will not consider bids without offsets.

The Czech government's procurement policy is illustrative. When it purchased a fleet of jet aircraft in 1999, offsets played a surprisingly large role. In reviewing bids from aerospace suppliers, the Czechs reportedly placed most importance on the offset package. Offset considerations made up 50% of their decision whether to buy from a seller, followed by technical specifications (30%) and financial factors (20%).^[7] This procurement policy departs from the price margin: the content of offset packages is supplanting price and quality competition of the base good.

Because procurement officials hope to achieve multiple and diverse objectives, it is not surprising that offsets vary considerably in design. A general model of offsets would, ideally, take into account the economic and political factors that codetermine policy. The following equation reflects these political economy variables:

$$\text{Policy} = f(\text{development strategy, transaction costs, market structure, political institutions, national security, bureaucrat maximization})$$

WELFARE EFFECTS OF OFFSETS

Governments know little about the welfare effects of offsets. Hooper noted that offsets are “a complex subject about which very little is known—they have

been described as smoke and mirrors . . . nobody knows who benefits.”^[8] Many governments view offsets as a beneficial tool for economic development. Development strategy today focuses on acquiring economic capabilities necessary to compete in the global marketplace. Offsets arise from the government's bargaining power in procurement and the belief that, for various reasons, it is more feasible to acquire these capabilities and benefits through non-standard contracting than in markets. However, although the government's purchasing leverage may enable it to extract rents from suppliers in an imperfectly competitive environment, there is no free lunch.

Economists are understandably skeptical when they observe any government intervention that subverts the invisible hand in markets. Orthodox economic theory has long vouched for the superior efficiency of markets and money as a medium of exchange (see, e.g., Refs.^[9,10]). In traditional arms-length exchange, competition in terms of price and quality drives buying and selling decisions. Goods and services exchange for money, which allows market participants to disassociate current production from consumption.

In offset arrangements, the buyer and seller may conduct a considerable portion of the procurement contract off the price margin. Offsets are thus susceptible to the double coincidence of wants inefficiency of barter. In addition, these arrangements are subject to extra administrative and bureaucratic costs that are less acute in markets. That said, the obvious question is “why do offset contracts persist today”? Studies demonstrate that offsets continue to flourish, in part, because they help build economic capabilities and are politically attractive.^[1,11,12]

OFFSETS AS A CAPABILITIES ACQUISITION STRATEGY

Economic capabilities are the skills and competences of a firm. The capabilities view considers the firm to be a pool of core and ancillary competences that become routinized over time to perform production activities.^f The ability of firms to grow capabilities internally and acquire capabilities externally explains many successes and failures in international markets.^[17]

The boundary of the firm—while always changing—depends on the transaction and governance costs of purchasing competences in markets, and the relative production cost differences between the firm and market competitors.^[18] The critical comparisons are therefore between the cost of cultivating capabilities internally, purchasing capabilities on the market, and purchasing final goods and services (off the shelf) in markets.

The government's aim in many countries is to promote the acquisition of the capabilities required to compete in high value-added markets. Most countries must purchase a majority of its information technology, aerospace, and defense systems in international markets because they have neither the budget nor the political support to arrange for indigenous production. Purchasing items off the shelf in markets is unlikely to transfer the capabilities required to produce these products. Ultimately, governments must decide whether it is more desirable to purchase capabilities (technology, skills, and routines) directly in markets, and/or develop capabilities over time by encouraging strategic alliances.

Many countries employ offsets as part of a broader economic development strategy. The offsets usually target high value-added industries and hasten the speed of technology dissemination from leaders to laggards. The main objective is to raise the level of economic capabilities in the targeted industry and, more generally, in the country.

We can view offsets as a government tool to enhance dynamic capabilities. Many offset arrangements transfer technological know-how, teach idiosyncratic routines, and forge long-term strategic alliances. Numerous studies have shown that these alliances “can be vehicles for organizational learning, helping

firms to recognize dysfunctional routines, and preventing strategic bottlenecks.”^{[16]g}

An implication of this reasoning is that *building* capabilities with offsets may be superior to anonymous, one-time *purchases* of technology in markets.^[11] For example, buying an advance-warning-aircraft-system off the shelf.^h may transfer some basic technologies and knowledge of maintenance operations; however, it is unlikely that the transaction will aid the purchasing country in the cultivation of new core competences. Long-term joint ventures cultivated through offsets may bear more fruit as multinational corporations are induced to teach the recipient cost-minimizing techniques.

BUNDLED GOODS

Another strand of research treats offsets as bundled goods.^[12] In this approach, the welfare effects of offsets may be either positive or negative, depending on the presence of economies (diseconomies) of scope and scale. Just as bundling can be shown to offer efficiencies under certain assumptions, the same can be said about particular offset arrangements. It is critical to note, however, that offsets, in the technical definitional sense, differ from bundled goods and services. To see why, recognize that the purchase of a bundle will only occur when the individual components are not sold separately or quantity discounts exist for the bundle, vis-à-vis buying the components separately. It is not unusual that neither of the above hold in offset contracting.

This approach is helpful but of limited use because the importance of capabilities, transaction cost, and public choice issues dwarf production economies. We need only observe recent government procurements to confirm that countries are often willing to accept production diseconomies to secure technology transfer and augment domestic capabilities.

For example, in the 1990s, Japan opted for a coproduction agreement instead of purchasing 200 F-15 aircraft off the shelf from a U.S. supplier. The relatively short production run in Japan resulted in severe diseconomies of scale. The total cost of coproduction to the Japanese was 2.5 times greater than the price for the aircraft in arms-length exchange with the American firm.^[4] Certainly, institutions and political economy variables played a crucial role in this procurement decision. International procurement is replete with similar contractual arrangements.

^fSeminal contributions to this literature include Penrose,^[13] Nelson and Winter,^[14] Chandler,^[15] and Teece and Pisano.^[16] The capabilities literature burgeoned after reaching a critical mass in the early 1980s. The work of Penrose on the theory of the firm is noteworthy.^[13] She was the first to argue that the boundary of the firm is a function of skills and know-how, not simply physical stocks of resources and technology. The capabilities approach acknowledges the contributions of transaction cost economics, but maintains that the boundary of the firm depends heavily on the number and type of skills and routines cultivated.

^gSee, for example, Prahalad and Hamel^[17] and Teece and Pisano.^[16]

^hA final good or service sold in markets. The production process is already complete.

CONCLUSION

Like other government policies, there are benefits and costs associated with offsets. Short-term gains for the targeted industries benefiting from an offset obligation are often visible and politically attractive. Under certain high-technology procurement settings, the offset may actually improve the efficiency of the exchange. In addition, a well-designed offset policy has been shown to contribute to the economic vitality of developing industries.

In a general equilibrium framework, however, the governmental action may result in a misallocation of resources and deadweight loss. Furthermore, because many offset obligations are not usually fulfilled for 5–10 yr, the long-run welfare effects on the purchasing economy will likely exceed the initial contract value.ⁱ Corruption, faulty contract design, and non-compliance in offset fulfillment must be vigorously monitored and addressed to reap the fruits of a well-conceived offset. A rich empirical investigation of this topic is not only warranted—it is needed in this time when governments are actively using these contracts as part of a dynamic economic development strategy. Many governments are currently experimenting with various kinds of offsets and other non-standard contracts in an effort to find efficient procurement instruments that can exploit government bargaining power. This heuristic process is slow and expensive; procurement officials would be wise to perform extensive analysis and auditing of offsets as recommended in Taylor and Brauer and Dunne.^[11,19]

ⁱPath dependency from the use of offsets is a potential by-product for some industries building complementary assets that are specific to a particular system.

Ombuds and Ombuds Programs

Tina Nabatchi

Lisa B. Bingham

*School of Public and Environmental Affairs, Indiana University,
Bloomington, Indiana, U.S.A.*

INTRODUCTION

This chapter discusses the role of an ombuds, a person within an organization who assists employees, stakeholders, or customers in resolving disputes by offering a wide variety of alternative dispute resolution (ADR) processes (for more information on ADR processes, refer to Nabatchi and Bingham in this volume; for more information on ADR in the public sector, refer to [Nesbit and Bingham](#) in this volume).

OMBUDS

Contemporary conflict resolution theory and practice suggest that organizations should design and build integrated conflict management systems, as opposed to a singular dispute resolution program, to better manage organizational conflict.^[1] In turn, many scholars and practitioners have asserted that an ombuds office is both a desirable and cost-effective element in an efficient dispute resolution system.^[2,3]

In Scandinavian countries, where the concept originated, an ombudsman, or an ombuds, is a public official appointed to hear citizen complaints and to conduct independent fact-finding investigations to correct abuses of public administration. The original word, *ombudsman*, is not gender-specific in Scandinavia; however, to avoid gender connotations, authors and scholars in the United States variously refer to an ombudsman as ombuds, ombudsperson, ombuds practitioner, etc. In the United States, the concept and function of an ombuds have developed differently, and have grown in both significance and prominence as they have blossomed in a number of public and private settings.

In the United States, an ombuds operates like a third-party neutral inside an organization by assisting employees, stakeholders, and/or customers of the organization in resolving workplace disputes through confidential, informal means. An ombuds has a diverse set of responsibilities and must serve many functions, such as supplying information and other resources, channeling communications, handling complaints, and resolving disputes.^[4,5] For these many functions, the

ombuds also plays a wide variety of roles, such as counselor, consultant, informal go-between, facilitator, formal mediator, and/or informal fact finder.^[6] Moreover, the ombuds uses various conflict resolution skills, such as listening, conflict coaching, facilitation, mediation, and shuttle diplomacy,^[6] but also has the ability to help individuals gain access to other informal or formal dispute resolution processes within the organization, such as traditional grievance procedures and equal employment opportunity (EEO) processes (for more information on grievance procedures, refer to Nabatchi and Bingham in this volume).

The ombuds serves an integrated function for the organization, and has the flexibility and capacity to handle numerous and varied disputes. In addition to providing assistance to people with complaints, concerns, and conflicts, the ombuds often also acts as an upward feedback mechanism, problem prevention device, and change agent in the organization.^[6] In this respect, the ombuds serves as a troubleshooter for the organization. An ombuds generally works closely with all personnel in an organization, from top-level management to front-line staff; therefore, an ombuds is often able to identify processes and practices that create employee (and other) conflicts, or that otherwise have negative effects on the organization. In this respect, the ombuds serves as a bellwether of organizational problems that could develop into lawsuits and as an early warning signal for new and emerging problems. Moreover, the ombuds may notice a pattern of problems, which suggests the need for policy or procedural change within the organization. The ombuds will try to eliminate these sources of organizational conflict through problem solving or brainstorming meetings, retreats, trainings, and other conflict management sessions. These features of an ombuds not only result in a more integrative and systemic approach to managing conflict in an organization, but also allow the ombuds to serve both a corrective and preventative role as a resolver of conflicts.

The effectiveness of an ombuds office depends on its ability to demonstrate confidentiality and neutrality—key principles in the ombuds profession. In terms of confidentiality, ombuds generally do not keep case

records, and the majority of their work is unknown to anyone except those who use their services.^[7] However, in the federal sector, there are certain exceptions to confidentiality for ombuds; in some circumstances, federal employees must report information when it relates to a felony, waste, fraud, abuse, corruption, or crimes by government officers or employees.^[8] These reporting requirements interact with federal statutes providing for confidentiality in dispute resolution.^[8] Similarly, state and local governments vary in the degree of confidentiality they afford dispute resolution processes involving administrative agencies.

In terms of neutrality, the ombuds must: 1) resist taking sides during a conflict; 2) possess no stake in the outcome of a dispute; and 3) demonstrate fairness, objectivity, and evenhandedness in relationships.^[4] To promote these qualities, the ombuds is outside of the organizational chain of command or reporting structure, and although all ombuds are made available and paid for by the host institution, not all ombuds are on the host organization's payroll. Some may work through a contract with another organization to provide an additional layer of neutrality.

OMBUDS PROGRAMS

Ombuds programs have been developed in both the public and private sectors. One reason for the growth of ombuds programs in the United States is that they are able to personalize the dispute resolution processes of large organizations such as corporations, municipalities, and government agencies. Thus, they provide people with individualized and flexible attention such that they are able to overcome the difficulties associated with the formalism and bureaucracy of large organizations. Today, ombuds programs are found in large corporations such as Haliburton (formerly Brown and Root), educational institutions such as the Massachusetts Institute of Technology (MIT), and government agencies such as the National Institutes of Health (NIH) and the Internal Revenue Service (IRS).

Ombuds programs can focus on different organizational constituencies. Traditionally, they provide services to those both within and outside the organization, including members of the public. In the federal government, most ombuds offices focus on organizational issues within the agency.^[8] In some cases, Congress established ombuds offices through legislation (e.g., Federal Deposit Insurance Corporation, Office of the Comptroller of the Currency, Small Business Administration, and State Department).^[8] In other cases, the agencies themselves created the office and staffed it with career employees insulated from politics (e.g., Customs Service, Federal Bureau of Investigation, Food and Drug Administration, and Department of Justice).^[8]

Research on federal workplace ombuds offices suggests that they can be effective when the EEO office has too many non-EEO complaints, or the employee assistance program (EAP) is receiving workplace complaints outside of its mandate. In addition, ombuds programs can be effective when personnel-related offices are not working together, employee morale is low, and employee-management communication is poor. Finally, such programs can be effective when there are poor labor-management relations and when there are frequent employee claims of retaliation.^[9]

BENEFITS AND RISKS OF OMBUDS PROGRAMS

Ombuds programs appeal to organizations for many reasons. First, many dispute resolution programs are accessible to a limited set of employees (e.g., those covered under collective bargaining agreements). In contrast, ombuds programs are accessible to everyone in the organization. Likewise, many dispute resolution programs are rigidly designed to handle specific types of disputes (e.g., those involving workplace contract or policy issues); however, ombuds programs are flexible enough to address typical workplace disputes related to contracts, policy, or law, but can also reach beyond these conflicts to handle individual and group disputes involving interpersonal issues, environmental problems, or racial and ethnic tensions. In short, ombuds programs are more inclusive of organizational personnel, can address a broader range of issues, and have greater ability to resolve conflict constructively and provide stability to the organization than single-process dispute resolution programs.

Second, most dispute resolution programs are reactive in that they only address conflicts that have been made "public." In other words, the programs respond only to disputes that have been formally expressed. Conversely, ombuds programs are both reactive and preventative: they can address formally expressed disputes, but can also address disputes where one party is unwilling or unable to publicly confront the other party.

Third, traditional dispute resolution programs focus on the symptoms rather than the source of problems. They engage in problem solving between the disputing parties, but not problem solving for larger organizational issues. Ombuds programs help identify and address the root causes of problems through systemic change. In theory, this allows an organization to decrease the highly visible costs of conflict and to increase organizational morale, productivity, and communication.

Finally, and perhaps most importantly, ombuds programs assist employees in finding fair solutions to

problems, and may facilitate problem solving at lower levels than would be necessary through traditional dispute resolution processes. This not only saves valuable resources for the organization, but also promotes a sense of justice, fairness, and participation among organizational constituents. Research shows that higher perceptions of justice in an organization lead to higher employee productivity and morale. Moreover, evidence suggests that people who learn how to effectively resolve disputes are more likely to resolve future disputes independently and more likely to teach these methods to other colleagues.^[10]

Despite the numerous potential benefits of ombuds programs, there are also some risks, especially if the ombudsperson violates guarantees of neutrality and confidentiality. One potential risk is that employers may distort the ombuds title in unilaterally adopted non-union arbitration programs. For example, one employer had its ombuds represent employees as their advocate in arbitration and select the arbitrator on behalf of both parties. After repeated selection of the same arbitrator who always ruled for management, it was clear that this particular ombuds was not neutral. Similar structures, where the ombuds departs from a neutral role, give the appearance of a conflict of interest. This reduces stakeholder trust in the ombuds office, which is a critical element for program success.^[11]

CONCLUSION

The use of ombudspersons continues to grow in a variety of settings, including educational institutions, hospitals, nursing homes, corporations, and government. Ombudspersons now have a professional association and a code of ethics.^[12] (For additional information and resources about ombuds and ombuds programs, refer to The Ombudsman Association (TOA) at www.ombuds-toa.org). As the benefits of ombuds programs are increasingly measured and understood, and

as conflict management theory and practice increasingly move toward dispute system design efforts and integrated conflict management systems, the prominence of such programs is also likely to increase.

Open Systems Theory

Rupert F. Chisholm

*Department of Management, Pennsylvania State University at Harrisburg,
Middletown, Pennsylvania, U.S.A.*

INTRODUCTION

Roots of open system theory date at least from the 1920s. At that time, scientists from several disciplines, including biology, philosophy, physics, and sociology, began to question prevailing mechanistic theories in their fields. For example, Ludwig von Bertalanffy, the “father” of general systems theory, observed that existing biological theories failed to explain the essentials of the phenomena of life. Instead, he advocated considering organisms as wholes, complex systems comprised of organization at various levels.^[1]

Thinking continued to develop in various disciplines over the next 25 years or so. In 1954, as a result of being located together at the Center for Advanced Studies at Stanford University, von Bertalanffy and several colleagues from diverse fields established the Society for General Systems Research. This organization aimed to identify commonalities of concepts, principles, and models in various fields to help transfer knowledge, increase understanding, and foster theory development among disciplines. Organizing the Society signaled a basic change in thinking about organizations and how best to understand and manage them.

THE NATURE OF OPEN SYSTEMS

Basically, a system is “a set of interacting units with relationships among them.”^[2] Organizations are a type of concrete (versus abstract) living system. Because all living systems are open (versus closed systems that have no transactions with an external environment), organizations are, by definition, open systems.

Fig. 1 gives a graphic representation of an organization as an open system. According to open systems theory (OST), all organizations (public, private, and non-profit) depend on the external environment to provide certain critical inputs to exist and carry out work over time. As the figure indicates, these required inputs include money, personnel, various types of materials and supplies, and information. The exact makeup of these critical inputs depends upon the industry, primary technology, strategy of the organization, and other contextual factors.

Transforming the critical inputs is the second phase of the overall process. Organizations transform required inputs into services or products that are exported back to the external environment. During this phase, an organization must “add value” to inputs brought into the system. Transforming inputs involves using various combinations of technologies. Technology includes all the knowledge, information, material resources, techniques, and procedures required to convert system inputs into outputs. For example, a road paving crew uses machinery and equipment, general knowledge, techniques, and information about the specific site to surface a segment of state highway. And, mental health staff members use various therapeutic techniques, knowledge of their clients’ individual, family and social situations, physical environments, and possibly medication to improve psychological functioning. As an open system, an organization must carry out transformation processes that produce services or products that meet the needs of other individuals, groups, or organizations in the outside environment. Only by consistently delivering services required by external constituents can an organization remain viable over time.

Exporting outputs to the environment comprises the third phase of the total process. Organizations produce several types of outputs: services and products, information, waste, and others. Some outputs are planned for and intended (e.g., the basic service delivered), and others are unintentional (e.g., the employees’ attitudes developed while delivering the service). As a result, an organization must attempt to clearly identify all key outputs and how they are perceived by stakeholders. To do this requires effective feedback from critical stakeholders (e.g., clients, employees, suppliers, sponsors) and other potentially important individuals, groups, and organizations. Receiving effective feedback is necessary to assure that the organization is producing and delivering valued services of the right kinds, at the right times, and in ways that are acceptable to recipients. And, as indicated below, receiving feedback does not occur automatically. Instead, it requires designing effective processes for constantly obtaining valid information about reactions to current services and service delivery and about basic long-term changes in the environment that may alter future service demands.

Fig. 1 Open systems view of organizations.

To summarize, organizations are complex systems that continuously interact with the external environment by importing critical inputs, transforming inputs into valued services and products, and exporting these services and products to the external environment. Because of the continuous input-transformation-output process, organizations depend upon the outside environment for their existence. And, to remain viable over time, they must deliver services (products) that meet the requirements of clients and other key decision makers outside the organization. Maintaining viability also requires designing and managing effective feedback processes.

KEY FEATURES OF OPEN SYSTEMS

Open systems theory also calls attention to several additional features that are important for understanding and managing organizations. These features include negative feedback, boundary, negative entropy, dynamic equilibrium, system levels, equifinality, and holism.

Negative Feedback

Feedback is crucial to the existence and functioning of organizations. According to OST, feedback is the flow of information back from the output phase to the input phase of the input-transformation-output process. The broken line in Fig. 1 represents this flow. Feedback can be positive or negative. Negative feedback, which indicates that the system is off course or is not meeting its goals, is most important for understanding and managing organizations. The house thermostat is an example of a simple negative feedback system. Here, the desired temperature is set, and when the actual temperature deviates above or below it beyond a prescribed limit,

this information automatically triggers an “on” or “off” switch. For many aspects of organization functioning, feedback does not occur automatically, and the process is considerably more complex than that of a thermostat. First, crucial processes that require feedback systems must be identified. Then these systems must be consciously designed, monitored, and managed. In addition, organizations must remain alert to make changes in the goals or standards against which to compare actual conditions as changes in the external environment and within the system occur.

Boundary

Following OST, a boundary is the imaginary line that separates an organization from its external environment. In Fig. 1, the oval surrounding the transformation process depicts the organizational boundary. Space outside the system boundary represents the external environment, E. A boundary carries out two essential functions for organizations: 1) it filters inputs and outputs; and 2) it binds internal system elements together and maintains system integrity. No system can exist and function if inputs of any kind or in unrestricted amounts are allowed to enter: it will soon disintegrate due to input overload. Therefore, each organization must make decisions and establish criteria that determine which inputs are permitted to enter, in what forms, in what amounts, when, and how. The boundary also operates during the output phase. In effect, the filtering qualities of a boundary result from the many decisions made, guidelines established, and constraints that emerge from formal and informal system functioning over time. By differentiating the organization from its environment, a boundary also helps hold elements of the system together. Members of the organization come to think of themselves as “insiders” and develop a shared view of themselves,

the organization, and the outside world. Over time, a unique organizational culture emerges that helps form and reinforce the boundary and provide coherence to the system. Although there are certain physical features (e.g., buildings, perimeter fences) that partially reflect boundaries, other aspects are primarily psychosociological (e.g., “I’m a Welfare Department employee”; “I’m a doctor at the XYZ Medical Center”). Establishing and maintaining appropriate dimensions and degrees of permeability of boundaries are crucial to maintain the system and achieve organizational effectiveness.

Technically, the environment [(E) in Fig. 1] includes everything outside the system boundary. However, complexity has led to conceptualizing the total environment as task and general environment.^[3] The task environment includes all the organizations, groups, agencies, and individuals that affect short-term organizational functioning. These include suppliers, information sources, regulators, customers, lenders, citizen groups, and others—any entity that can affect goal setting and goal attainment activities of the system. The general environment is the environment that exists beyond the task environment: legal, social, political, economic, technological systems that surround and provide the context for the organization and its task environment. Future opportunities and new constraints on organization actions emanate from the general environment. Consequently, organizations must be proactive to identify and determine the implications of emerging forces in the general environment and reactive to feedback from the existing task environment. “Opportunistic surveillance” is required to discover and create opportunities for an organization and to maintain long-term system health.^[3]

Negative Entropy

Negative entropy (negentropy) results from the open system nature of organizations. The entropic process is a universal law of nature in which all forms of organization move toward disorganization and death.^[4] Following the second law of thermodynamics, over time, physical systems tend toward states of maximum disorder and toward a leveling of differences. In contrast, open systems tend to become more elaborate through the differentiation of internal structures and processes. Greater complexity can emerge because of the basic design and dynamics of the system. It is made possible via continuous transactions with the environment. Conceptually, the process of differentiation can continue indefinitely provided the system continues to generate sufficient negative entropy (negentropy). Organizations as open systems can generate negentropy in many ways: by attaining

favorable ratios of inputs to outputs, by improving the internal alignment of internal components and processes, and by improving location in and linkages with the external environment. Acquiring information about basic changes in the general environment, how these provide future opportunities, and realigning the organization with emerging external conditions can provide substantial negentropy. Theoretically, an infinite number of possibilities exists, and each organization must strive continuously to discover and invent ways of sustaining the negentropic processes.

Dynamic Equilibrium

Organizations as open systems operate in states of dynamic equilibrium. Such states mean that, despite constant movement which results from continuously importing, transforming, and exporting inputs and outputs and internal system dynamics, an organization tends to remain in a steady (but not static) state. In a steady state, forces that act to influence a system in one direction tend to be offset by countervailing forces in the opposite direction. Using Lewin’s^[5] force field diagram is one way to conceptualize this phenomenon (see Fig. 2). Here, factors affecting phenomena in organizations (e.g., quantity of output; quality of work) are represented as driving and restraining forces. At a particular time, driving forces to change the level of quality or quantity of output tend to be offset by restraining forces in the opposite direction. These offsetting forces are not necessarily precisely equal, but they tend to keep the organization functioning within certain upper and lower limits and maintain system integrity. This feature is called “dynamic equilibrium.”

Dynamic equilibrium results from two types of basic systems processes. First is primary regulation, which results from interactions that naturally occur among components of the system or between the organization and the external environment. For example, behavioral norms emerge spontaneously from interactions that occur among organization members as they carry out work activities. Similarly, informal roles also emerge over time from spontaneous interactions inside the organization and with individuals in the external environment. These naturally occurring phenomena are aspects of primary regulation processes of all social systems that help structure expectations, attitudes, and behavior and make employee collaboration and cooperation possible.

Secondary regulation results from consciously designing feedback systems to regulate key system processes. Budgets and management information systems are examples of such regulation. Katz and Kahn^[4] identify the necessity of having appropriate feedback systems for organizations. However, because secondary

Fig. 2 Force field representation of factors determining current level of work group output.

regulation tends to limit the potentiality (number of possible future states of a system) of the organization,^[1] proliferating secondary regulation processes is not necessarily desirable. Such proliferation may lead to inflexibility, inability to respond quickly, and lack of capacity to perceive new opportunities in the environment. Bureaupathology^[6] can result from overemphasis on such formal control mechanisms. In short, organizations must carefully consider using both primary and secondary regulatory processes. For example, team-based organizations rely heavily on primary regulation to improve flexibility and response time. Organizations also must monitor and redesign these systems to meet new requirements.

System Levels

Another important OST principle is that systems exist at several levels. Miller,^[2] for example, identifies the levels of cells, organs, organisms, groups, organizations, societies, and supranational systems for living systems. For organizations, primary levels include the individual, group, organization, society, and trans-societal. Two things are important about system levels. First, each system level has certain emergent features not found at lower levels of complexity that affect system functioning in highly relevant ways. To illustrate, group norms, roles, and values affect group and member functioning to a considerable degree. And, these factors are not present at the individual level that is immediately below the group level. Second, systems exist within systems. The group is a subsystem of the organization (the suprasystem), that, in turn, is a subsystem of the society, its suprasystem. Hence, within an organization, group functioning is strongly affected by features of the organization. And, as an open system, societal norms and values influence actions of the total organization, as well as those of groups and individuals within it. Linkages among system levels also

lead to the influence of subsystems on higher levels (e.g., groups on organizations or organizations on society). In general, the effects of higher-level systems on those of lower levels is greater than the reverse. Because systems exist within systems of greater complexity and a given system depends on the higher-level systems for critical inputs (and for accepting outputs), understanding an organization best starts at the next higher level or from the outside in. Following this OST approach, organizational analysis best starts with the environment, where the organization is located in it, its basic orientation to it (vision, mission, strategy), and how it carries out basic transactions with the environment.

Equifinality

Traditional organization and management concepts were based on a mechanistic model of human beings and of organizations. Taylor's^[7] scientific management, in particular, attempted to determine the "one best way" of conducting work operations. The theory of bureaucracy and classic management principles also rested on closed system, deterministic logic—"doing 'x' will result in 'y.'" Much current organization and management theory remains rooted in such thinking. In contrast, OST states that reaching a desired state or a particular set of goals can be achieved in many different ways (equifinality). Thus, organizations in the same industry can succeed following quite different strategies and using diverse designs. Relatedly, a given set of starting conditions does not necessarily lead to an expected set of outcomes (multifinality). For example, having the best educated, most highly qualified employees does not guarantee having the most effective organization. In short, as open systems, organizations have considerable flexibility to determine how to reach a particular set of goals (end state). And, establishing certain starting conditions does not guarantee reaching a predefined set of goals. These

two principles mean that managers have considerable latitude to create and design structures and processes that meet the particular requirements of an organization.

Holism

Holism involves the essential quality of organizations as open systems. Ideally, this OST principle means that “the whole is more than the sum of its parts.” Put more precisely, the statement should read, “. . . *can be* more than . . .”. For, with open systems, this is a possibility, not a guarantee. The synergy that occurs under certain conditions to make decisions of effective groups or organizations superior to those of individual members illustrates holism as a positive phenomenon. At the same time, as indicated in the previous section, because open systems are far from deterministic mechanical systems, group decisions also can be of lesser quality than those reached by individual group members (e.g., Bay of Pigs invasion). Thinking about organizations should include the potential of the holistic principle and also an awareness that this phenomenon does not automatically take place.

IMPLICATIONS OF OST

Contrasted with earlier mechanistic closed system views of organizations, OST provides a revolutionary perspective for thinking about and managing organizations. The following statements highlight several important implications of this perspective.

1. Open systems thinking emphasizes the criticality of the external environment in providing required inputs, in determining the acceptability of outputs, and in affecting appropriate design of internal structures and processes. This basic dependency on the environment suggests that understanding an organization best starts from the outside and works inward. Attempting basic organization change should proceed in a similar way.
2. Understanding environmental demands and constraints on an organization is essential to understanding organizational functioning. However, the environment does not dictate organization design. Rather, equifinality indicates that there is more than one route to organizational effectiveness. And, because each organization is unique in certain important

ways (e.g., development history, culture), an organization must attempt to develop its own design and ways of operating to reach optimal effectiveness.

3. OST emphasizes the dynamism inherent in organizations. This dynamic quality stems from never-ending interaction with the environment, dynamic equilibrium that maintains the organization and key processes within certain limits, the tendency to generate negative entropy, and negative feedback. Focusing on the dynamic nature of organizations as open systems helps reveal the severe limitations of traditional static views of organizations as closed mechanical systems. OST challenges theorists to continue to develop improved models that increasingly capture more of the dynamic, ever-changing nature of organization.
4. Open systems thinking also focuses attention on maintaining the input-generating capacity of the external environment. Because organizations rely on the environment to provide critical inputs, concern about the ability of the system to generate inputs indefinitely into the future must exist. Otherwise, individual organizations create conditions that make future sustainability impossible. In short, from a long-term perspective, organizations cannot determine how well they are doing for themselves without determining how well they are doing for the suprasystem (environment).^[8]

Operations Research

William L. Waugh Jr.

*Department of Public Administration and Urban Studies, Georgia State University,
Atlanta, Georgia, U.S.A.*

INTRODUCTION

Operations research or management science involves the development of mathematical models to simulate real-life problems. The goal is to design, analyze, and improve the performance of a system or process. By examining the structure of a problem, analysts can search out optimal solutions. Models may be created to examine the operation of a wide range of systems, including financial, engineering, industrial, and administrative systems.^[1]

The roots of operations research can be traced to the pre-World War II period. British research on military deployments used radar to track aircraft, and scientists termed part of the project “operational research.”^[1] During the war, operational research techniques were applied to submarine warfare, strategic bombing, and other military problems. War-related research involving chemists, physicists, statisticians, mathematicians, and planners began using the same quantitative tools.^[2] Following the war, the techniques were applied to financial, industrial, and governmental problems. As the field developed in the 1950s, professional societies were formed, first in Great Britain and the United States and then elsewhere. Since the postwar period, the applications have increased and become more specialized. Now, operations research is the term commonly used in industry and engineering, and management science is the term commonly used in dealing with administrative systems.^[1]

THE PRACTICE OF OPERATIONS RESEARCH

Operations research begins with the construction of mathematical models to represent real-life phenomena, such as systems and processes. The modeling begins with the identification of a problem or issue to be studied. The controllable and uncontrollable aspects of the system or process, the goals or purposes, and the constraints or limits are identified. Data are collected to approximate as best as feasible the attributes of the model. When the model is operational, analysts must then determine the extent to which the model

represents reality and how applicable their findings will be to the real-life problem.

Complex models are possible, but care has to be taken to make sure that the complexity does not interfere with the development of practical solutions. Simplistic models may be sufficient and, in many cases, are preferred, because they are easier to explain to decision makers. The development of algorithms, the “sequence of operations that can be carried out in a finite amount of time,”^[1] to model problems may be easy or may even be impossible. Not all problems are solvable. The size of the problem, the number of steps in the process, and the availability of data may confound analysis. Optimality may have to give way to practicality. The nature and size of the error may make optimization difficult if not impossible. Suboptimal solutions may be the best that can be expected.

The practice and methodologies of operations research have grown with the development of computer software and hardware. New PC-based software provides tools for dealing with specific classes of problems, and the expanded capacities of hardware are making it possible to include many more variables and much more data in the models. It is also making it possible for individual managers to use operations research/management science techniques for the growing number of decision-making situations that they face in the workplace. Specialized software is increasingly available through Internet “libraries” sponsored by professional organizations as well as private vendors.

Operations research has been used to address a wide variety of problems in the public and non-profit sectors. It has been widely used by the Department of Defense in much the same ways it was used during World War II. It has been used for bus scheduling, postal delivery and mail sorting, waste management, land use regulation, highway safety, education, and agriculture.^[3] Some common operations research/management science techniques follow.

The Linear Programming Model

The linear programming model is one of the most common operations research/management science

technique. This is a class of models in which the objective function, a principal criterion representing effectiveness (e.g., profit maximization or cost-efficiency) and the constraints on the system or process (e.g., time, human resources, and financial resources) can be expressed in linear terms. There may be more than one or even no optimal solution. There may be no feasible solution, as well.

Network Analysis

Network analysis deals with the linkages among elements in a system. Networks are common in a variety of systems, including highway systems, aviation flight patterns, utility grids, and communications systems. Path analysis, the analysis of paths between and among centers or nodes, can provide solutions to flow problems, such as traffic routing and cost of problems. The flow of work can be analyzed and decisions made concerning how to speed up or improve the quality of the work. PERT-CPM (Program, Evaluation, and Review Technique and Critical Path Method) is a common tool to analyze projects and to determine how they may be made faster and more cost effective.^[4]

Integer Programming

Integer programming is useful in dealing with systems in which one or more values cannot be a fractional. For example, industrial processes typically do not manufacture incomplete products, such as half of an automobile or a fourth of a laser disk, and administrative processes typically do not serve fractions of individual clients or employees.

Non-Linear Optimization

Non-linear optimization provides tools for dealing with problems that are non-linear in nature. The tools can accommodate processes that are non-sequential or in which variables change at different rates. For example, doubling the speed of computer processors does not necessarily double the speed of computations, because other variables affect the speed of computations.

Markov Process

Markov processes are useful in dealing with processes that are probabilistic, where decisions have to be made based upon data that may be uncertain or, in some cases, missing. Prior event probabilities are used to predict the probabilities in the subject system.

Queuing Theory

Queuing models are commonly used in dealing with systems in which people are queued or in line, situations in which customers or clients may be waiting for service and decisions need to be made concerning how many servers are necessary to satisfy the demand. The number of customers and system capacity have to be weighed against the acceptable length of waits and costs.

Simulation

Simulation or observing the behavior of a model to see how it operates so that improvements can be made is also a relatively common operations research technique. Simulations permit the examination of interactions among variables in a system when researchers vary the conditions. One or a few variables may be changed to analyze the impact on the model.

There are also a wide variety of decision analysis techniques, including game theory, decision trees, and utility theory, to explain decision making. Knowledge about the psychology of decision making, including non-rational approaches, is also applied. Also, there are heuristic techniques that can be applied to help identify optimal decisions.

CONCLUSION

Operations research/management science techniques have been invaluable tools in many decision-making and problem-solving contexts. The British and American efforts in World War II are illustrative of that utility. The application of quantitative techniques has greatly aided public, non-profit, and private decision makers in finding better solutions to engineering, industrial, financial, and other administrative problems. Financial resources can be allocated more efficiently; school buses can be routed more effectively to reduce wait times for students and costs to school systems; construction projects can be managed better to reduce time and other resources; management systems can be streamlined; communications systems can be designed to link organizations and individuals more effectively; garbage pickup can be managed to reduce costs; and so on.

The use of such techniques has not been without critics, however. While few argue that the techniques have not been of benefit in many instances, many argue that sometimes the techniques have been misapplied. Rational decision processes, of which operations research and management science are examples, may best be applied at the level of operational decisions.^[4,5] Policy-level problems are usually less clearly defined,

and the goals are less likely to be solely economic. Not all decisions are simply technical, without social and political implications. In short, efficiency and speed are not always the preferred values, and optimal solutions based on those values may be less important than consensually derived solutions. Policy decisions, in particular, may be characterized by intense disagreement over means and goals. For the products of operations research, i.e., the “optimal” solutions, to be accepted and adopted, there need be some sensitivity to the political context of the solution and the need for compromise, little strong opposition to and at least some support for the solution, some attention to jurisdictional prerogatives, sensitivity to the goals of society and the real goals of the decision makers, congruence with societal, group, and individual goals, no offsetting side effects, and achievement of prior results cheaper and faster.^[6]

There are biases inherent in operations research/management science. Operations research has been described as “value free,” because the techniques have been used in a variety of contexts and often with a single-minded focus on efficiency, without attention to the normative issues raised. It is difficult to quantify some values and, in quantitative decision-making processes, non-quantified values tend to be undervalued. Indeed, it is argued that some values, some of the most important social and political values, cannot be quantified or to do so distorts their importance.

Time and data constraints, as well as the nature of the problems being addressed, dictate flexibility in

analysis. The application of operations research techniques is less important than the identification of practical solutions to problems at hand. Operations research techniques offer sets of tools that can be used along with other sets of tools. They are particularly effective at the operational level, where efficiency is the goal. They are much less effective at the policy level, where efficiency is less important than other goals, and optimal solutions are less important than politically acceptable solutions.

Orange County Bankruptcy

Susan MacDonald

California State University, Stanislaus, Turlock, California, U.S.A.

INTRODUCTION

The Orange County Board of Supervisors filed for [Chapter 9](#) protection from bankruptcy on December 6, 1994, declaring losses in the county's investment pool of approximately \$1.7 billion or roughly 20% of the entire pool. At the time, there were 187 government units, in addition to the county, participating in the Orange County Investment Pool (OCIP). Many of the participants were cities or towns located in the county; a few were towns outside the county's geographic limits that had asked to participate because of the county's record of high yields. All of the county's school districts were invested in OCIP because state law required them to be. Finally, regional water, transportation, and other special districts participated in the pool, although their involvement was voluntary.

Groups had been drawn to the investment pool, in part, because it was large and represented a wealthy county. Median family income was around \$48,500, fifth highest in California, and total property values were estimated between \$100 and \$150 billion. These and other wealth indicators gave investment pool managers access to a greater variety of financial instruments, lower fees by brokers and other financial advisors, and access to more expert and timely information than many other local government investment pools.

The county's treasurer, Robert Citron, had been in office since 1970, having secured voters' confidence in seven elections, the most recent being that in June. He had also been recognized for his financial accomplishments by the County's Board of Supervisors and by groups like *City & State* and the American Society of Public Accountants, which had pronounced him an "outstanding public official" during the treasurer's re-election campaign. The pool itself had repeatedly outperformed the state of California's investment pool. Between the recession years of 1991 and 1993, OCIP produced returns between 8% and 9%, while the state generated returns in the range of 5–6%. The differential meant additional revenues to Orange County of approximately \$250 million per year. Further, in October 1994, Merrill Lynch had underwritten a \$110 million bond issue to which both Standard and Poor's Corporation and Moody's Investors Services had accorded the county the second highest

rating, AA. Residents had re-elected County Treasurer Robert Citron that June—only six months before the bankruptcy. John Moorlach, Citron's opponent in the campaign, had made the Orange County Investment Pool, and its level of risk, the central issue in the campaign. Nevertheless, citizens re-elected Citron by more than 60%.

UNDERLYING CAUSES

Accounts of the bankruptcy clearly blame Citron for the debacle, but most trace the origins of the county's difficulties to the passage of Proposition 13 in 1978. Double-digit inflation in the 1970s had affected both citizens and the state. Those with assets, like the State of California, wanted to preserve their assets' value, which was being eroded by inflation. As early as 1975, California's Auditor General recommended that state and local agencies be allowed to invest in both security loans and reverse repurchase agreements, then illegal. Security loans would make it possible for a California agency to lend a stockbroker or financial institution one-year Treasury notes worth \$100,000; in exchange, they would receive cash or a promissory note *in excess of* the Treasury note's current market value as well as regular interest payments or dividends. Reverse repurchase agreements resembled security loans except that the contract was verbal instead of written and a date of repurchase was specified. In its report, the Auditor General estimated that the state and local agencies held more than \$7.8 billion in assets, and that in any single day as much as \$175 million could be temporarily transferred to financial institutions, providing an additional net income to California agencies of \$3 million per year.

While state officials introduced measures to preserve their assets, California *citizens* were taking steps to preserve theirs. Californians, especially retirees, were experiencing the effects of inflation with *both rising prices* and the *taxes* that they paid. Retirees on fixed incomes were not affected by bracket creep in their income tax as much as in their *property taxes*. For some time, counties had been reassessing property values and raising the tax rates applied to housing; by 1977–1978, some retirees were paying more in annual property taxes than they had initially paid for

their homes. This fueled the movement for property tax reform and Proposition 13.

Proposition 13 accomplished several things. First, it stipulated that all properties that had not been sold in two years (i.e., 1976–1978) would have their assessed values returned to 1975/1976 levels. Properties that had sold during this time would be valued at their market rate. Second, it set a ceiling for property tax rates at 1% of the property's value, and limited increases in the assessed value of property to 2% annually. Third, a provision, little noticed before the proposition's passage, made allocation of property tax revenues the prerogative of the state. To cope with this unsolicited responsibility, legislators passed AB 8 in 1979, establishing a formula for reimbursing property taxes to counties and other local governments. The formula was based largely on the city or county's *history of taxation and predisposition to self-tax in 1978*, as well as the unit's range of responsibilities and access to other sources of revenue. Finally, AB 8 required that 2/3 of the state legislature or voters, whichever was appropriate for the tax measure at issue, approve any future tax increases.

Historically, Orange County's taxes had been low, at least by California standards. This meant that the Legislature's formula for redistributing property taxes did not favor the county. County officials had tried to make legislators aware of their predicament. A study by the State's Legislative Analyst's Office, conducted after the bankruptcy, reported that in 1996/1997 Orange County received only \$40 in property tax revenues per person from Sacramento,^[1] placing it second from the bottom of all California counties. That year property tax returns to counties ranged from \$38 to \$1167 per capita, with the statewide average at \$106.

In the years immediately following Proposition 13, California was able to offset losses in county revenues with a special bailout. This stopgap measure sufficed as long as the economy remained strong and state tax receipts held up. These conditions held in California until the late 1980s. By 1987, however, strains were beginning to show. In August that year, Orange County officials testified before a joint hearing of the Senate and Assembly local government committees that they would be forced to lay off as many as 140 staff to meet the budget shortfall that year. Unable to accommodate the county's request for additional financial support, the Legislature adjusted the county's responsibilities for state mandated services.

Counties in California serve *three* functions—as administrative arms of the state, service providers for all county residents, and municipal service providers for those who reside in the county but outside the limits of any city. In their state administrative role, counties provided health care, welfare, and court services, and managed elections. Property taxes covered many

of their county and municipal services, as well as matching support for their state administrative responsibilities. Unfortunately, funding from the AB 8 formula was not adequate for all counties. Recognizing this, the Legislature passed at *least 9 bills* liberalizing county investment policies and as many as 19 bills overall between 1978 and 1994 relaxing safeguards on local government investments.^[2] The most important of these for Orange County were AB 346 in 1979, which authorized the use of reverse repurchase agreements, and AB 3576 in 1992 that enabled treasurers to invest as much as 20% of their portfolios in a variety of collateralized mortgage instruments. The Legislature accompanied this move toward greater autonomy with a relaxation of reporting requirements. In 1983, it passed SB 389, which eased the quarterly reporting requirements of local treasurers in effect since 1933. Although replaced the following year with stricter reporting requirements, these were allowed to expire in 1991. In 1993, the Legislature made treasurers' reports entirely voluntary.

In sum, Proposition 13 reduced the property taxes collected by counties and placed control for the taxes that were collected in the hands of the California Legislature. These measures hurt all counties, but affected Orange County more than most because the formula disadvantaged those with lower tax rates in 1978. This, in turn, forced local officials to look to non-traditional sources for revenue. One of these was greater development, because new housing was priced at market rates and could be assessed special fees that lay outside the parameters of Proposition 13. It also led officials to seek alternate sources of revenue, including new investment opportunities.

The impact was evident in the distribution of county revenue sources; property taxes, once accounting for more than 30% of all county revenues, fell to just over 15% in 16 years. In the meantime, *other revenues*, that had accounted for less than 1% of all county revenues in 1977–1978, rose to almost 3% by 1994. In Orange County, *other revenues* represented 12% of all revenues in 1993–1994, while property taxes contributed only 13.3%.

FINANCIAL INSTRUMENTS

Two investment miscalculations are generally credited with causing the bankruptcy: excessive use of derivatives and the leveraging of Orange County's financial portfolio. Derivatives are financial instruments, whose returns *are derived from* an underlying stock, commodity or other asset *other than* interest. Frequently, the return will be calculated by a formula, such as the difference between short- and long-term interest rates.

In 1994, more than 70% of the OCIP was invested in federal agency notes. These financial instruments are issued by U.S. government agencies and corporations, rather than by the U.S. Treasury. As such, they provide somewhat higher yields and carry a little more risk than Treasury bonds or notes. In OCIP, these agency notes were split 60–40 between those with *fixed-rate yields* and those with *floating rates*. The floating-rate notes thus accounted for almost 30% of the overall pool. Floating-rate notes differ from other agency notes and are often referred to as *structured notes*; they greatly resemble derivatives, both in their management of uncertainty and their difficulty to price. Structured notes, like other securities, have two components: principal and interest; however, their yields vary considerably.

The simplest structured note is one in which the yield *varies with* interest. These notes have great appeal because they adapt to market conditions, allowing the value of the principal to remain unaffected by the market, but providing higher yields when interest rates rise. A more complicated note is the *inverse floater*. This structured note provides yields that are *inversely related* to interest rates, usually calculated using the London inter-bank offer rate or LIBOR. For example, if the six-month yield (represented as 180/360 days) on a \$100 million note were set at 9% minus LIBOR and LIBOR were at 8%, the yield would be calculated as: $\$100 \text{ million} \times (9 - 8\%) \times 180 / 360 = \$500,000$. Inverse floaters may carry upper and lower limits within the formula to prevent negative yields. While the yields on inverse floaters may be attractive, the notes themselves are almost impossible to price. In the 1990s, large financial institutions purchased supercomputers for the sole purpose of calculating the prices of these and other complex financial instruments.

Federal agencies like the Federal National Mortgage Association (FNMA or Fannie Mae), the Federal Home Loan Bank (FHLB), the Federal Home Loan Mortgage Corporation (Freddie Mac), and the Student Loan Marketing Association (Sallie Mae) issue structured notes like the ones purchased by OCIP. The FHLB ventured into this area in 1986, in the aftermath of the savings and loan debacle, to protect federally subsidized mortgages against inflation. In 1994, *Orange County held \$100 million of FHLB structured notes*. In 1992, when LIBOR was at 3.625%, the yield on these notes was 8.25%, or, \$2,687,500 in the formula just cited; by November 1994, when LIBOR had risen to 6.5%, the yield had *declined to 2.5%*, or \$1.5 million in the same formula—almost half of the former yield. John Moorlach, Citron's opponent in the campaign for county treasurer, understood this dynamic; how much others did remains an open question. Nevertheless, neither the financial instruments nor their percentage distribution in the pool were illegal in California.

Leveraging is a form of borrowing that involves the use of existing assets to purchase *additional* assets. It might be compared to a home equity loan, which is normally obtained to make home improvements, with the house itself being used as collateral. If the home equity loan were used, instead, to purchase a second house, and that second house later sold at a profit, the home equity loan could be repaid in full, with interest, and the borrower might still make a profit. Citron essentially borrowed money against existing assets in OCIP (usually government agency bonds) in order to purchase additional assets (again, government bonds). However, since public borrowing is restricted by the California constitution, he purchased *reverse repurchase agreements* to accomplish this. At the time of the bankruptcy, Citron had leveraged almost \$7.5 billion into a fund worth \$20 billion, in effect *almost tripling the size* of his investment pool.

In the latter part of 1994, when it was clear the OCIP was in trouble, Citron repeatedly referred to *paper losses* in the pool—losses that he apparently believed would *not* be realized because he believed in holding securities to maturity. By leveraging his assets, however, through reverse repurchase agreements, *Citron exposed the bonds to market fluctuations*. This market exposure could have been mitigated with sufficient cash to repurchase the bonds. Citron had started the year with over \$1 billion in cash, so he had reason to believe that the losses *might* have remained only on the books. However, in February 1994, the Federal Reserve raised the discount rate from 3% to 3.25%. While the economy in California remained stagnant, business activity in other parts of the country was expanding and the Fed grew concerned that inflation would undermine the solid gains already made. By year's end, the Federal Reserve had raised the discount rate *six times*—an *unusual* but not unprecedented action.

By October 1994, OCIP's cash reserves had declined from over \$1 billion to less than \$450 million. Matthew Raabe, Citron's assistant, alerted the county's chief administrative officer, Ernie Schneider, to the problem. Schneider employed the services of Capital Market Risk Advisers (CMRA) to assess the pool's finances. Capital Market Risk Advisers found that OCIP had already lost \$1.5 billion and that there was not sufficient cash on hand to meet the interest payments coming due in December on voter-approved bonds. The crisis was precipitated when Crédit Suisse First Boston (CSFB), holding a \$110 million FNMA note with the county's promise to repurchase, announced its intent to sell the note on the market if Orange County did not come up with sufficient cash. The county had only \$100 million on hand. Crédit Suisse First Boston then announced its intent to call in *additional loans* of \$1.2 billion. County administrators

had explored other options to liquidate their portfolio, but sunshine laws governing their meetings, and time pressures from the banks, forced them into bankruptcy to prevent a run on their remaining assets.

In 1990, the state of California faced the first of several multibillion dollar budget shortfalls. The national economy had been slowing since 1989, but the end of the Cold War, with its concomitant reductions in defense expenditures, hit Californians particularly hard. Between 1990 and 1993, California lost 400,000 jobs and its unemployment rate jumped from 5.8% to 9.4%. This not only meant that the state could no longer afford to subsidize counties for their loss of property tax revenues, but that it would be forced to take extraordinary measures to address its own fiscal crisis. The state delegated many services to counties, *increasing* their costs.

THE AFTERMATH

Orange County citizens largely blamed *government* for the bankruptcy, as demonstrated in their June 1995 vote. [Chapter 9](#) had prevented participants in the pool from withdrawing their assets and protected the county from creditors, but it had *no effect on the general obligation bonds* the county had issued, which were coming due in 1995. In order, at least in part, to honor the county's commitment to bond holders, the newly appointed county administrator, William Popejoy, recommended a *sales tax increase* of one-half cent, *limited* to ten years for the county. This would have taken the sales tax from 7.75% to 8.25%. California counties share sales tax revenues with the state, but Orange County would have received the entire half-cent increase had Measure R passed, still returning 6.0416% to the state. Measure R required a 2/3 vote. Despite extensive publicity, Measure R was defeated with only 39% of those voting endorsing the proposition. In postelection polls, 70% of those who rejected the measure said they did so because they opposed new taxes under *any* circumstances or they did not believe they should pay for *someone else's* mistakes. To Wall Street and others in the financial community, such action was tantamount to an *abrogation of contract*. Indeed, the voters' refusal to honor their debt was almost as shocking as the bankruptcy itself; it undermined the very principle of security that has long been associated with public debt and that continues, at least in theory, to justify lower yields in the public sector.

The aftermath also witnessed numerous investigations into the causes and consequences of the bankruptcy—both official and unofficial. State courts found both Robert Citron and his assistant, Matthew Raabe, guilty of misappropriating public funds and

securities fraud. With Citron, it was not only that he had lied to investors about the safety of the investment pool, but that in the months before the bankruptcy he had illegally transferred funds across accounts in an attempt to forestall the inevitable. In the end, Citron served no time in jail but was fined \$100,000 and allowed to perform community service at the county jail for ten months. In granting Citron this leniency, the court recognized the treasurer's extensive co-operation with the investigation. Matthew Raabe, the Assistant Treasurer who had initially reported the problem to the Board of Supervisors and served very briefly as county treasurer, was not as fortunate. Raabe had had little role in devising the investment strategy but had full responsibility for explaining it to investors. Raabe was also found to have been involved in the illegal transfer of interest from the investment pool to county coffers when the county's financial strategy started to unravel. In May 1997, he was convicted on *five counts* of misappropriating public funds and securities fraud, later sentenced to three years in prison, and ordered to pay a \$10,000 fine. Throughout most of the proceedings, Raabe had insisted upon his innocence, arguing that he had been a loyal subordinate following the orders of his immediate supervisor.

State Superior Court proceedings were initiated against several others, but no one was convicted or judged negligent. Non-criminal charges of willful misconduct were dropped against two members of the Board of Supervisors. The budget director, Ronald Rubino, was implicated in the misappropriation charges, but a jury failed to agree on a verdict. Later, he pleaded no contest to one misdemeanor and received 100 hr of community service. The county brought charges against Merrill Lynch in both federal criminal and civil court. After two-and-a-half years and 5000 pages of testimony, Judge Capizzi allowed Merrill Lynch to settle the criminal suit for \$30 million. A civil suit for \$2 billion was settled out of court in June 1998 with Merrill Lynch agreeing to pay \$417 million in exchange for the county's dropping all of its charges. Merrill Lynch also returned \$20 million in county funds it had been holding since the bankruptcy. Other investment firms also settled with the county. KPMG Peat Marwick L.L.P. settled for \$75 million in 1998. LeBoeuf, Lamb, Greene and MacRae agreed to restore \$12 million to the county's Community College District, making it the first depositor to have been refunded in full. Finally, CSFB settled with Orange County for \$55 million in May 1998 after CSFB had been sued by the Securities and Exchange Commission (SEC) for fraud and deceptive securities practices, hastening the bankruptcy.

The State Auditor, Kurt R. Sjoberg, focused on Citron and the county's investment strategy. Sjoberg found

that Citron had exposed the county to excessive risk by failing to observe the basic public investment priorities of safety, liquidity, and yield. This was due, as we have seen, to the leveraging arrangement accomplished through reverse repurchase agreements and the purchase of interest rate sensitive, structured notes at a time when interest rates were rising. In addition, the Auditor noted that Orange County had managed several pools: a commingled investment pool, a commingled bond investment pool, and several separate investment accounts. The State Auditor recommended to Legislators that they restrict reverse repurchase agreements to 20% of a unit's portfolio, prohibit the use of debt for speculative purposes, require regular financial reports, and establish a prudent person rule for all local investment officers.

The California Senate's Special Committee on Local Government Investments cast the blame more broadly. Committee members attributed the bankruptcy to a "lethal mixture of corporate and political culture, where the public trust has taken a back seat to corporate profit and political expediency."^[3] Specifically, they recognized that Citron had sacrificed the conventional standards of safety, liquidity, and yield for higher profits and had done so by imprudently leveraging the pool's assets. At the same time, they acknowledged that 35% of the county's *own source* revenues had derived from interest income and that there had been tremendous pressure on the Treasurer to offset the post-Proposition 13 shortfall in county revenues; accordingly, they charged the Board of Supervisors with inadequately supervising the Treasurer's activities. Members did not limit their criticism to Orange County, however; they castigated bond-rating agencies for failing to identify any risk in the county's portfolio and charged them with actively contributing to the bankruptcy. The committee also drew attention to both Moody's and Standard and Poor's responses to John Moorlach's 1994 challenge when both agencies accused him of engaging in political rhetoric. The committee found this intrusion into the political debate at the *very* least unprofessional. It also criticized securities agencies and brokerages for failing to recognize the portfolio's risk. While the advisory group did not go so far as to include financial advisers among those *responsible* for the bankruptcy, it did blame securities firms for *narrowly interpreting* their role and charged them with "insufficient regard for the special nature of public funds."^[4] Finally, the committee drew attention to the *victims* of the bankruptcy—the 187 cities, schools and special districts that had invested in the pool and whose savings were now in jeopardy. Rather than spare them, however, it charged them with abrogating their own fiduciary responsibilities by failing to raise questions about the pool and the treasurer's

investment strategy. In effect, the Special Committee suggested that officials reaped the benefits of Citron's strategy while being unwilling to delve into its details for fear of what they might discover.

The Securities and Exchange Commission conducted several investigations in the aftermath of the bankruptcy. Among the more salient were investigations into the securities activities of county officials, the influence of brokerage firms in crafting state investment legislation, and the potential conflict of interest of firms like Merrill Lynch in advising public officials. It censured Citron, Raabe, CAO Steiner, and four members of the Board of Supervisors for misleading and defrauding pool participants, although no formal admission of guilt was required or fine extracted. The parties did agree not to violate securities law in the future. While the SEC found no direct evidence of misconduct on the part of brokerage firms in the passage of state legislation, it did issue subsequent rulings prohibiting campaign contributions to officials with securities responsibility within two years of any formal transactions. It also worked with investment banks to develop *self-regulating procedures* in which the firms will disclose to the SEC information on their trades, risks and customers. Finally, the SEC developed educational packages on derivatives and strategies of risk management for state and local officials and promulgated *new rules* making brokerage firms legally responsible for taking their public clients' financial goals and *fiduciary responsibilities* into consideration when advising on investments.

The financial community responded to the bankruptcy with increased reliance on bond insurance for managing municipal debt. Prior to the bankruptcy, only municipalities with low bond ratings had been required to take out insurance; afterwards, bond insurance became almost commonplace for a while. It was the financial community's way of protecting investors against citizen abrogation of their debt responsibilities and this increased the public's cost of borrowing.

Public administration scholars responded to the bankruptcy, and the events in its aftermath, either by focusing on the risks involved in derivatives purchasing and portfolio leveraging, or by concentrating on the normative aspects of public finance and the fiduciary role that public investors must also assume. Less attention was paid to the fact that the only person actually to spend any time in jail was Ken Raabe—Robert Citron's appointed administrator in the Treasurer's Office.

Organization Development

Gerald T. Gabris

Division of Public Administration, Northern Illinois University, DeKalb, Illinois, U.S.A.

INTRODUCTION

Organization development or “OD” as most practitioners refer to it, eludes simple definition. Nonetheless, several attempts to define OD provide perspective. W. Warner Burke defined OD as “a planned process of change in an organization’s culture through the use of behavioral science technology, research and theory.”^[1] French and Bell provided a similar assessment of OD as “a top-management supported, long range effort to improve an organization’s problem-solving and renewal processes, particularly through a more effective and collaborative diagnosis and management of organization culture—with special emphasis on formal work team, temporary team, and inter-group culture.”^[2] In both definitions, OD was linked to a planned change effort in an organization’s culture using social science technology. Burke went so far as to state that when an OD effort takes place, there is no OD if no change in culture occurs.

Yet other practitioners and scholars defined OD in even broader strokes. Robert T. Golembiewski suggested that OD be best understood as a “stool.”^[3] Moreover, he goes on to say that the denotation of “stool” he is referring to involves the three-legged small-chair motif, where each supporting leg represents part of what OD does. In this perspective, OD involves attempts to modify the “structure” of an organization. This is a particularly common OD focus in the public sector.^[4] Yet, OD often involves cultural interventions in the context of working toward more responsible and mature interpersonal relationships. Finally, OD may involve the development or reformulation of organizational policies. In this sense, OD is a multifaceted discipline that may focus on multiple targets, all aimed at helping an organization address a perceived need or problem.

Frequently, but not always, OD utilizes an external consultant, known as an intervenor, who collaboratively works with the organization to diagnose problems and to help design potential solutions (known as interventions). This leads to another important aspect of OD as an organizational discipline.

OD is Value Loaded

The genesis and emergence of OD as an organizational change framework did not emerge from a vacuum but

from the rich history of human relations management beginning in the 1940s. Leading scholars and nascent practitioners such as Kurt Lewin, Douglas McGregor, Rensis Likert, Robert Blake, and Chris Argyris, to mention just a few, imbued OD with a deep-rooted appreciation of the human element and human values in the work environment. Risking some oversimplification, OD began to stand for:

- Employee dignity and respect.
- Employee participation in decision making.
- Responsible freedom and autonomy.
- Treatment of employees as mature adults.
- Stress on employee growth.
- Development of meaningful jobs.
- Recognition of human potential and value.

Given these values, OD strives to avoid conventional models of consultation, where the consultant serves merely as an external expert or as a physician to a sick patient.^[5] Instead, OD considers the role of external consultant as a collaborator, a catalyst, a role model, and as someone who will take a stand for advancing the human value of employees in the work organization. Given this value-loaded perspective, why do organizations opt for an OD problem-solving approach, and what do they hope to gain from it?

OD AS DISTINCT FROM CONVENTIONAL MANAGEMENT CHANGE MODELS

OD does not suggest it is for everyone and all organizations. Unlike many conventional approaches to organization improvement that advocate a one-size-fits-all model [see *The One Minute Manager* (Ref. ^[6])], OD utilizes an open-ended discovery process for designing potential solutions to perceived problems. In OD, this process is called “action-research.”

As W. Warner Burke avers, in practice, the words “action-research” are reversed, because research is usually conducted before action takes place.^[1] Action-research, a term originally coined by John Collier^[7] and Kurt Lewin,^[8] refers to the “methodology” common to most OD efforts. Although not

always in tidy, lock-step sequences, action research involves:

- Identification of a felt need.
- Diagnostic research to assess the need.
- Feedback between a consultant and client.
- Collaborative problem solving (intervention).
- Evaluation of results.
- Termination of effort or more diagnosis followed by more feedback and intervention.

A key point is that in OD, it is not assumed that a problem exists and the nature of a problem is not speculated until a client organization feels a strong enough need to do something about it. Once a felt need surfaces, OD consultants conduct research to obtain a better handle on the nature and depth of a particular problem, so that any treatment addresses the causes and not simply the symptoms of a nettlesome issue. Feedback is used to test the diagnosis. If feedback suggests that the problem has been identified correctly, and if the need to do something remains intense, then a collaborative design between the client organization and consultant to address the problem ensues. A collaborative design partially insures that the client organization assumes a degree of “ownership” for the solution and will actively commit to making it work. Subsequent evaluation assesses the degree of success achieved by the intervention and can provide perspective on what, if any, additional steps should be taken. According to Golembiewski, the degree of OD intervention success in the public sector for the United States approaches 85%.^[4]

WHAT KINDS OF THINGS DOES OD DO FOR A CLIENT ORGANIZATION?

Fundamentally, OD customizes planned change processes around the specific needs of the client organization. Nonetheless, several intervention technologies recur frequently as strategies for dealing with a panoply of problems or issues. It should be repeated that these technologies are not utilized randomly as panaceas to organizational problems, but instead, are only applied after careful analysis suggests the best intervention for a given situation. Further, intervention technologies have evolved over time, and new ones are continually emerging, so those described below are just the tip of the iceberg.

In the 1950s and 1960s, a primary intervention tool employed by OD’ers involved “training groups” which have also been called T-Groups or laboratory groups. Typically, managers and executives from different (stranger) organizations would become participants in a larger group led by a trained facilitator. These groups would generate their own data for

discussion (they served as their own laboratories) based on open-ended comments and observations made by group participants. No particular problem was preidentified for discussion. Groups could explore just about any issue they wanted. From these sessions, participants honed their own communication, confrontation, and interpersonal skills which could then be brought back to their home organizations. In this way, T groups could help “seed” work organizations with persons possessing progressive interpersonal skills and abilities, thus enabling their organizations to grow and adapt more effectively.

While some practitioners lament the passing of T-Groups, and in particular, the group facilitation skills these sessions imparted on those leading the sessions,^[3] other more targeted and specialized group interventions have come to predominate the tool bag used by most OD practitioners. The term used most often to describe this category of interventions is “team building.”^[9]

To the casual observer, team building may simply involve the notion of coworkers cooperating nicely on group projects. Having employees work together on joint projects, communicating openly, and developing creative solutions while avoiding conflict may certainly be one aspect of a sound “work team.” Yet in OD parlance, “team building” involves a much larger array of potential intervention strategies based on diagnostic results. Golembiewski, Munzenrider, and Stevenson^[10] provide insight into this idea by differentiating between “conflicts of agreement” versus “conflicts of disagreement.”

Suppose an external consultant asks labor and management within the same client organization the following simple questions:

1. What is going right in this organization?
2. What is going wrong in this organization?
3. What should be done to correct any problems?

Now, it may evolve where labor and management perceive the same things going right, the same things going wrong, and have in general the same solutions—but for some reason, they have not communicated these to each other. Under this scenario, they may think they are in disagreement, when in fact, they agree, but do not know it. Hence, each may act on its own, thinking the other party does not understand its position. This is a crisis of agreement. Here, just showing the labor and management groups that they actually agree may be sufficient to focus energy on joint solutions. Alternatively, the same diagnostic questions may show the two groups to be in genuine disagreement. They may hold different perceptions as to what problems exist and what should be done about them. The point is that the type of team-building strategies utilized for crises of agreement may vary substantially from crises of disagreement.

If crises of disagreement are found to exist, then third-party interventions involving conflict resolution, confrontation, and similar interaction-centered designs may be appropriate.^[10] Here, the need is to get the parties to a dispute talking and thinking about ways of mitigating conflict. Here, the intervenor may serve as an effective go-between, trying to construct an acceptable third party, neutral, consensus-based contract. These types of team building interventions may take a long time to implement, may involve several meetings, and may require detailed agreements between opposing parties.

Alternatively, if crises of agreement prevail, more task-centered team building may be appropriate. Simple examples may include strategic planning, goal setting, role analysis, visioning, and creative problem solving. Usually, interpersonal conflict is low in such situations, thus allowing the group to focus on tasks rather than on interpersonal relationships. Again, the type of team building that works best may vary from situation to situation.

OD has a much greater range of intervention techniques than T-Groups and or team building. Another whole area of intervention can be referred to as “process consultation.” Whereas team building tends to focus on concrete, tangible problems or “content,” process consultation focuses on organizational processes. The concept of process consultation was first described by Edgar Schein as a kind of consulting philosophy or attitude toward helping individuals and groups within organizations.^[5] He goes on to define process consultation as “a set of activities on the part of the consultant that help the client perceive, understand, and act upon the process events that occur in the client’s environment in order to improve the situation as defined by the client.”^[5] As such, process consultation is not a technique or set of techniques, but an approach to consulting.

Schein points out that all organizations have many processes they take for granted but that nonetheless can cause problems if not managed properly or if misunderstood. Examples of processes include communications, problem solving, decision making, and role playing. A process consultant will carefully “observe” how a client organization behaves in performing these processes. The process consultant does this by blending into the work environment in the least obtrusive manner possible, so as to gain the trust of workers and to open channels of communication. Over time, the consultant may become cognizant of patterns of behavior that have implications, say on interpersonal relationships that are either misunderstood, unknown, or misperceived by the client. When the consultant feels the client is ready for feedback, the consultant’s observations may be made known, and then, both may work toward a collaborative solution.

A concrete example of how a process may be misperceived involves group decision making. The chair of a group may summarize ideas about an issue and then ask if anyone has additional comments to make before a decision is made. Silence ensues, so the chair assumes all group members are in consensus. Later, the chair learns that two group members dislike the decision but remained quiet fearing that their views would not be taken seriously. Unless this attitude and behavior of certain group members was made known, the chair could continue making decisions under the guise of consensus, when in fact, intense disagreement may be more the case. Process consultation involves working through such troubling process-based situations over time.

Besides team building and process consultation, OD possesses many other intervention technologies and strategies, too many to describe in such a short encyclopedia entry as this. Some worth mentioning include job design and structuring,^[11] pay policies and incentives,^[12] stream analysis,^[13] and burnout and stress management.^[10,14] One could go on. For an excellent summary of potential consulting interventions, see Golembiewski’s *Handbook of Organizational Consultation*.^[15]

CONCLUSION

Organizational development is a powerful tool in the quiver of arrows available to managers for improving public organizations. Never has it claimed to be a panacea or complete solution to all problems. On the contrary, OD should be used sparingly and in situations where it has a high potential for success. The client organization has to want to do OD. There must be a strongly felt need for this type of approach to succeed. OD involves total system change, its aim is to move the organization in a planned direction and in a way that respects human value and dignity. Hopefully, this brief discussion may help some public managers have a better sense of what OD might be able to do for them. OD exists not to reinvent the status quo, but to challenge it and to open new vistas. Only the client organization under the guidance of a skillful OD practitioner may know when the time is right. Might the time be ripe to at least consider this possibility?

Organization Theories, Types of

Robert T. Golembiewski

Department of Political Science, University of Georgia, Athens, Georgia, U.S.A.

INTRODUCTION

One classic view of types of organization theories implies that they were much ado about little or nothing. As the doggerel of an earlier day put it:

Over forms of organization,
Let fools contest;

Whatever is best administered

Is best.

The basic approach here is more demanding and less definitive. Broadly, the present view is that forms of organization matter: given different situations and their features, different structures will have different consequences, even profoundly different consequences. At times, more or less, we will be able to urge that a specific structural model has bad→good fit with specific situational features. This case was first made in comparing conditions of turbulence versus placidity, and the fully developed comparisons were labeled “situational theory.” The bureaucratic model is better suited to placid environments, while structural innovations are appropriate for turbulent conditions. The latter case refers to more complex technologies, rapid change, and complicated product lines with shortening half-lives.

Moreover, a second kind of “fit” also relates to structure. Students of management often talk about “best practices” or “good practices,” but that is inelegant as well as incorrect. A practice may have good or bad or indifferent effects, in general; but more specific predictions will depend on the organizational structure and culture into which the practice is inserted. Commonly, even what most regard as a “good practice” may have inconsequential or even “bad” effects when incautiously inserted into the wrong structural contexts.

NOTES ON A TAXONOMY OF STRUCTURES AND THEIR CONSEQUENCES

More about such important issues associated with protean forms of “goodness of fit” will come later.

Immediate attention turns to an ideal way of dealing with structural issues in the aggregate, as well as to the present state of our reach-and-grasp in this central particular.

A General Ideal Model

Fig. 1 sketches an ideal taxonomy for present purposes, focusing on a matrix of organizational types or archetypes as well as on the “marker variables” that will provide texture and tone to the similarities and differences within or between the archetypes. A complete form of the ideal typology, that is to say, will provide two kinds of information about organizations that will permit confident and comprehensive description and prediction. Thus, that ideal will be built around an exhaustive catalog of organization types; and the typology will provide differential content for the several archetypes via a large number of “marker variables,” e.g., percentage low or high on involvement, participation, and so on. In plainer words, that ideal will identify distinct categories of organizations as well as the particular features on which the categories differ or are similar. The two cornerstones of the matrix have simple labels: they label each archetype; and these labels may be descriptive (such as High/Authoritarian–Low Participation–Low Involvement collectivities), or they may be clinical (e.g., paranoid), or they may reflect some of both.

The Present Taxonomic Status

We are a long way from having a relatively comprehensive version of the taxonomy that Fig. 1 illustrates, but several important points seem significant enough about the progress that has been made. Thus:

- The number of archetypes is not known, and perhaps there never will be a maximum: the working versions now differ widely on this central particular and, absent specificity about archetypes, cumulative research is highly impossible. Why? Directly, proportions of archetypes will differ in specific research batches in unknown ways, and often this will obscure or camouflage any associations that seem

		Organizational Archetypes			
		I	II	...	N
Marker Variables					
1	Structured Variables (e.g., centralization)	High	Low		High
2...	Style Variables (e.g., coercive)	Low	High		Low
.					
.					
N	Population Variables (e.g., authoritarian)	High	High		High

Fig. 1 Sketch of a useful taxonomy.

- to exist in one batch or another. Hence, the “mixed” character of existing research.
- Recently, statistical techniques have been developed to isolate patterns of differences and similarities for many collectivities described by numerous variables. Early aggregations now identify 10 to 12 archetypes (e.g., Ref.^[1]), but the number of archetypes may be subject to periodic expansion, as we become more capable of finer tuning.
 - Most organizational research neglects nuances distinguishing the archetypes, and focuses on associations between two or a few marker variables in an organization.^[2] This constitutes a major reason why research results are mixed.
 - The mixed results often have suggested to some that nature is chaotic and, hence, essentially unknowable. The present belief is that this goes much too far, but the truth remains: tests of associations between marker variables in relation to taxonomies have been largely restricted to the study of individuals (e.g., Ref.^[3]).

In sum, the existing confusion in the organization behavior literature is understandable, and perhaps even unavoidable. But perhaps, also, we will soon begin cumulative work toward a comprehensive taxonomy, as the next section suggests.

Some progress toward organizational archetypes

If incomplete, some noteworthy progress has been made toward isolating a panel of organizational archetypes; and both progress and limitations get attention here. Progress can be illustrated conveniently by some long-standing descriptive work on the bureaucratic and flow-of-work models. This progress gets illustrated by two kinds of efforts: orientations toward budgets and forces toward greater or lesser productivity. Large volumes of detail are available elsewhere. To rely only on this author’s research, useful summaries are possible of clinically oriented descriptions of consequences of

the two models (e.g., Refs.^[2,4–5]), as well as related to substantive issues (e.g., Ref.^[6]). In Fig. 2, conveniently, activities A+B+C yield some product or service.

Toward Two Basic Archetypes

For many decades now, archetypal description has focused on two basic models. Reasonable but incomplete confidence can be placed in these alternative descriptions, and their consequences will be sampled. All in all, the samplers are perhaps best described as pre-archetypal forms or descriptions on their way to archetypal forms.

Some consequences of bureaucratic model

With predecessors extending at least from biblical days, the bureaucratic model has dominated in organizations. Fig. 2A provides skeletal details for this model. In details as well as in substance, overall, Fig. 2A can with relative safety be associated with a broad range of deleterious consequences, on average. Consider only three sets of these probabilities.

First, S in Fig. 2A tends to have particularistic biases, at the expense of systemic achievement. For example, Supervisor B in the bureaucratic model is generally motivated to increase budget and policy support for B activities, while S_A and S_C have similar motivation for focusing on A and C, respectively. And, that is the way matters should be, and will be, given only there that a minority of cases in which people can transcend self-interest over the long run. Reinforcing this tendency, M_{ABC} typically has no valid and reliable ways to assign costs to each S; and all Ss often will resist having costs assigned to their unit, and especially when any doubt exists, which is the usual case. Hence, one common feature of life in bureaucratic models: what is inelegantly but accurately described as throwing dead cats in the backyards of other units to avoid budgetary costs.

A

- departmentation is based on separate functions or activities
- reporting relationships are vertical
- span of control is small: only a few subordinates report to any supervisor

B

- departmentation is based on total flows of work
- reporting relationships are both vertical and horizontal
- span of control can be large

Fig. 2 Two pre-archetypal forms: (A) Basic bureaucratic model, (B) Flow-of-work model.

Consider, second, a related awkward feature of Fig. 2A structures: they encourage a downward orientation in output levels. To explain, only all three S units can raise output in the bureaucratic model, but any single S unit can and does in a Fig. 2A structure induce powerful forces to lower output.

The greater convenience of lowering versus raising output does not inevitably lead to reduction, but the effect is powerful, given the bureaucratic model.

Finally, with respect to an amalgam of control and responsibility, common powerful pressures in the bureaucratic model generate awkward consequences in any single S units, and especially at the beginning or end of sequences, like $A \rightarrow C$. If the S_C unit decides to reduce output, that may leave the other two units no reasonable choice but to go along or foolishly maintain higher levels. In the latter case, S_C might argue with some force that this only proves the basic point: that activities A and B are simpler, and also that the plain record justifies additional resources for C.

Some consequences of flow-of-work model

Arguments contrary to the samplers above can be generated for Fig. 2B structures; which gained great and growing popularity in the past 3 or 4 decades. At senior levels, this alternative often is called the “divisional model” (e.g., Ref.^[7]); and at low levels of

organization, this structure is associated with job enrichment and enlargement as well as with cross-training and job rotation.

Cross-training and job enrichment and enlargement are common prescriptions for organizing work today, and they are disingenuously often recommended as best or good practices while retaining the bureaucratic model. That is awkward advice, but it can only succeed despite itself and at the common cost of low levels of probability. Thus, cross-training in Fig. 2A requires the participation of all three supervisory units. This is clearly more difficult than in Fig. 2B, where each supervisory unit can engage in the project, or not, and with each having the direct opportunity to pay any costs while reaping all benefits.

Similar differences characterize each major stage of cross-training innovations, including selection of trainees, training, evaluation, and real-time application of any learning. Perhaps basically, Fig. 2A places the major burdens on each S, but with M_{ABC} the major recipient of any positive consequences, and one can easily go broke betting in favor of such an outcome. This is obviously an arrangement that requires Ss to transcend their immediate self-interests. Most undercutting is this obvious fact: in Fig. 2A, there is no direct way in which (for example) As cross-trained in B can put their greater mastery to direct use in their home unit. In Fig. 2B, in contrast, any S unit provides

sufficient scope for the full set of innovation stages, with all appropriate rewards and punishments being experienced in each involved S unit. To illustrate, direct applications of any cross-training consequences are possible in Fig. 2B structures in each S unit. Here, positive consequences of cross-training may be diffused from the positive experience of even a single S unit—possibly and even probably. In Fig. 2A, reliance often must be placed in command→obey dynamics, which have their serious limitations, and especially where bureaucratic structures encourage narrow self-interest.

Four central points

These structural comparisons could be extended broadly, but four central points will carry that burden here. First, and of greatest practical and theoretic significance, the failure of most good practices reforms is encouraged by retaining the basic structure of work. To illustrate, even desirable innovations or recommendations for (e.g.) cross-training can die as add-ons in the context of a traditional structure (e.g., Ref.^[8]).

This amounts to a bandage that leaves the basic cause in place. Basic structural change typically cannot be finessed without costs, in sum, even though this crucial detail usually gets neglected.

Second, the basic Fig. 2A versus B contrasts are here illustrated at low levels of organization, but a similar case can be developed at higher levels of organization around such flow-of-work alternatives as products (e.g., Ref.^[6]). Indeed, Fig. 2B most prominently appeared in the “division model”^[7] in research directed at large units of business organizations.

Third, the comparative relevancies of alternative structures is no Johnny-come-lately. To be sure, the higher-level limitations of the bureaucratic model were emphasized influentially in business (e.g., Ref.^[7]) and only later in government (e.g., Refs.^{[2],[5]}). But, the essential dynamics were clear at early times in both arenas (e.g., Refs.^[9–12]).

Fourth, the choice of a structural model often is influenced by considerations other than comparative dynamics, so a structural model must be accepted politically as well as generate better effects. This may seem paradoxical, but the two conditions do not necessarily occur together. For example, in U.S. Social Security operations, movement from a Fig. 2A to a 2B structure was accompanied by major increases in morale and productivity, as is to be generally expected (e.g., Refs.^{[4],[6]}). Detailed contrasts develop the point (e.g., Refs.^{[6],[13]}). While these positive effects were still being felt, however, Social Security officials became enamored of computer applications, which to them implied the need to return to a Fig. 2A structure. This is a conventional view but, for reasons far beyond the present goals, is more common than convincing or necessary.

Toward organizational archetypes: basic limitations

In sum, as the brief summaries above indicate, two preliminary archetypes permit some real progress toward comprehending structural dynamics in organizations. But, “some” is clearly not enough, as two points will illustrate for present purposes: a distinction between “mock” and “real” structural forms, and a review of what several observers see as useful elements in a full set of archetypes that eventually will comprehend organizational phenomena.

“Mock” Versus “Real” Theories

As Gouldner (Ref.^[14]) advised early on, any prescriptions can be differentiated in application as “mock” or “real,” to focus on only the simplest form of the distinction. To illustrate, a mass transit system articulated a set of reporting relationships and associated policies that could be labeled bureaucratic, but under the press of “building the railroad”—a multibillion dollar undertaking with tough schedules and tight budgets—many modifications and clear contradictions with those prescriptions were acted on, and even agreed to (e.g., Ref.^[15]). To a substantial degree and for many purposes, then, a “mock” formal infrastructure may be said to have existed but was often superseded by conscious but limited efforts at planned change.

Each of the structures in Fig. 2 can be “mock” to various degrees, and that makes for some consequential differences in the associated dynamics. For example, a “mock” version of Fig. 2A seems unlikely to generate “effective centralization,” but determined efforts by a charismatic leader might succeed in that effort even though bureaucratic structures can contribute to “chaotic localism” in ways already suggested above, e.g., in lowering rates of production or in multiple veto centers.

This is not to say that “mock” artifacts are always *faux*, or impotent, in addition. In the mass transit authority, for example, once the rail system was in operation, changing coalitions-of-interests began to vivify some of the “mock” features and to hold people responsible for what the system earlier prescribed but only incompletely acted upon (e.g., Ref.^[15]).

How Many Models is Enough?

The simple contrast above implies that Fig. 2 does not provide enough theoretical power, and that basic point can be reinforced by a brief review of other efforts toward taxonomies of organization theories. Thus, your author recognizes that two models are not sufficient, although they can support useful analysis. Elsewhere, (Ref.^[16]) your author provides substantial

detail about a third form—the matrix model—which adds usefully to the two models in Fig. 2.

Others go substantially further, and this acknowledges that Fig. 2 provides only a useful start. Thus, Mintzberg's (see Ref.^[17]) clinical synthesis provides for six structural variants:

- The “machine model” like that in Fig. 2A.
- The “professional bureaucracy,” which is much like Fig. 2A but features the addition of often complex staff and other services.
- The “entrepreneurial structure,” which focuses on a charismatic central figure who innovates and supervises an organization with little middle management support.
- The “professional organizations” in which the technically skilled employees work under flexible supervisors, ideally informed by guiding standards.
- The “innovative organization,” or *ad hoc*-racy, which relies on temporary and often-spontaneous infrastructures for specific purposes.
- A divisional structure like that in Fig. 2B.

Clearly, Mintzberg incorporates the conceptual territory covered by Fig. 2 and pushes substantially beyond it. Other exemplars employ advanced statistical methods to aid in such pushes (e.g., Ref.^[1]).

CONCLUSION

The work on organization theories, then, represents progress but only at early developmental forms of a full taxonomy. Basically, extended versions will provide increasingly powerful tools for description and prediction. The goals are that a progressively comprehensive set of archetypes will be described, and their consequences as well as covariants will be specified with substantial and growing accuracy. Beyond that, such comprehensive taxonomies can guide systemic change, as illustrated by first efforts at motivating a different structure for the U.S. federal system.^[5]

Despite some progress, versions of a complete taxonomy now lay basically in our future. Existing theories and models serve many useful purposes, but they nonetheless fall substantially short of what can be envisioned in some detail. Usefully, however, analytic ways to approach that ideal seem to have recently become available.

Note also that levels of “good fit” will have to be accommodated. Thus, this description suggests the many ways in which Fig. 2B structures have a poor fit with the bureaucratic model. At a macro level (e.g., Ref.^[5]), Fig. 2B structures also have major features of poor fit with American constitutional features. Moving beyond the bureaucratic model in

government, thus, in short, features challenges beyond those encountered in the business arena.

Organizational Citizenship Behavior

Courtney E. Jensen
Larkin S. Dudley

Center for Public Administration and Policy, Virginia Polytechnic Institute and State University, Blacksburg, Virginia, U.S.A.

INTRODUCTION

Organizational citizenship behavior (OCB) is a fairly recent concept that draws on a variety of disciplines including political science, psychology, economics, and sociology. This article defines OCB and describes concepts related to it; presents the organizational theories from which OCB is derived; explains the relationships between OCB and attitudes, personality, and leadership; and highlights OCB's role in organizational effectiveness.

DEFINITION AND RELATED CONCEPTS

The term OCB was coined by Dennis Organ and his colleagues in the early 1980s.^[1] It has come to be defined as “individual behavior that is discretionary, not directly or explicitly recognized by the formal rewards system, and in the aggregate promotes the efficient and effective functioning of the organization.”^[2] Actions that constitute OCB must not be required in the job definition and the rewards for such behaviors must not be contractually guaranteed. While there is no consensus as to which components define OCB, the five dimensions suggested by Organ that have received the most empirical research include:^[2,3]

1. *Altruism*: Targeting helping behavior toward a specific individual.
2. *Consciousness*: Adhering to the spirit in addition to the specifics of the rules and norms.
3. *Sportsmanship*: Not complaining about trivial matters.
4. *Courtesy*: Consulting with others, preventing problems from occurring, and mitigating them when they do.
5. *Civic virtue*: Being aware of and involved with issues that affect the organization.

The concept of OCB shares some overlap with prosocial organizational behavior, organizational spontaneity, and extra role behavior, but the term it is most closely associated with is contextual performance. Instead of concentrating on outputs or task

performance, contextual performance focuses on activities that support the social and psychological environment.^[4] The major difference between OCB and contextual performance is that the latter makes no reference to what is expected and concentrates on the social/psychological contexts that will enhance technical task performance rather than the environment that will bring about optimal organizational effectiveness.^[2]

ORGANIZATIONAL THEORY FOUNDATION

Organizational citizenship behavior can be traced back to the work of Barnard and Katz and Kahn.^[5,6] Barnard believed people's commitment or “willingness to cooperate” was essential and could not be acquired through a contractual obligation or obedience to authority. Katz and Kahn argued effective organizations have three obligations: 1) attract and retain employees; 2) ensure employees adequately function in their roles; and 3) encourage behavior that exceeds the minimal performance requirements. The third obligation creates an environment favorable for OCB as a sense of citizenship encourages a contribution beyond what is contractually required.^[2]

Other theories that have contributed to shaping OCB include the work of Roethlisberger and Dickson, who drew a distinction between the formal and the informal organization, the latter being a necessary condition for collaboration.^[7] The dual ideas of collaboration and informal organization comprise the essence of OCB.^[2] Another theory from which OCB draws is leader-member exchange theory that posits differences in subordinates abilities, causing leaders to treat them in one of two categories—hired hands and cadres. The relationship between the leader and the hired hands is contractual but the relationship with the cadres is fluid so the leader can negotiate through social exchange extra contributions that are likely to resemble what defines the behaviors of OCB.^[2] Somewhat unexpectedly, the theory of transaction cost economics that views the contract as the essence of the market exchange acknowledges behavior that fits with the concept of OCB. According to transaction theory, employees make three contributions. First, they satisfy

the agreed upon tasks of the contract and second, they contribute those actions not specified in the contract but that the employer may ask for in the future. Akin to OCB, the employee contributes spontaneous actions neither originally specified nor explicitly ordered.^[2] Finally, OCB shares some similarities with the concept of the clan in that the employees see their interests as similar to the interests of others and the organization as a whole. This leads to promoting each other's interests and a sense of community.^[2]

JOB SATISFACTION, ATTITUDES AND PERSONALITY

Organizational citizenship behavior researchers have hypothesized that job satisfaction, attitudes, and some personality factors should predict an individual's propensity toward OCB.^[2] When Barnard observed that the willingness to cooperate fluctuates, the natural question was what causes that fluctuation to occur? The concept of OCB materialized from research on one possible explanation—job satisfaction. Since OCB has the ability to take many forms and can be found in a myriad of situations, many of which are unpredictable, researchers often want to link it to job satisfaction.^[2] In trying to link job performance and job satisfaction, some researchers discovered that the connection between performance and satisfaction is weak. Others found that a relationship only emerges when satisfaction results from performance-based rewards. Propositions about job satisfaction have thus shifted to propose that improving the relationship between performance and rewards can strengthen the relationship between job performance and job satisfaction.

Attitudes and personality are good prognosticators for patterns and behaviors over time in ambiguous situations and may moderate any relationship between OCB and job satisfaction. Attitudes can come to the surface during varied situations that fail to offer compelling incentives for performance. Closely related to attitudes' moderating effect on satisfaction is the notion of trust or fairness. Actions that constitute OCB are part of a social exchange and in order for that exchange to continue to take place between the employee and the employer, the employee must perceive a sense of justice or fairness in the organization. The overlapping concepts of perceived fairness and job satisfaction are key components of the idea of morale, which in turn is a major motivational factor for OCB.^[2]

Personality's relation to OCB is best understood under the umbrella of the Big Five framework of personality capturing a wide array of personality traits in five broad categories, including agreeableness,

conscientiousness, emotional stability, extraversion, and openness to experience.^[8] The two categories that have important relevance for OCB are agreeableness, which relates to helping, courtesy, and sportsmanship; and conscientiousness, which relates to compliance and civic virtue. However, in research, personality has proven to be the weaker predictor compared to attitudes for a number of possible reasons. First, personality may have more of an indirect result by affecting attitudes that in turn effect job satisfaction. Second, it is possible personality influences the manner and motive of OCB more than its actual substance. Finally, there is the possibility that the workplace inhibits and restricts personality in some ways.^[2] Overall, there is not one dominant attitude or personality trait for predicting OCB, but in nearly every study, morale is consistently linked to an individual's OCB.^[2]

LEADERSHIP AND PERFORMANCE

One reason there is no equation to easily determine OCB is it may include the employee's desire to contribute along with his or her feeling of obligation to contribute. Leadership plays an important role in the employee's determination. Leaders can encourage OCB by clarifying what is expected, by determining how employees can achieve what is expected, and by expressing concern for the employees' personal well being.^[2] Treating employees fairly may motivate them to engage in OCB because the perception of fairness may create a sense of obligation, increase trust that contributions to the organization will be rewarded in the future, improve job satisfaction, and engender a greater regard for managers seen as kind and fair.

However, other factors may intervene negatively on the development of OCB, including organizational constraints, conditions that make it difficult for employees to perform their duties, thus reducing the ability and the motivation to perform OCB; an individualistic organizational culture, which is more likely to discourage OCB than a collectivist culture; and a widening power distance between managers and employees, which may affect the employees perception of fairness, a precondition for OCB.

From the point of view of leadership, managers tend to value OCB if they perceive it enhances organizational effectiveness. It is difficult to prove a direct correlation between OCB and organizational effectiveness but researchers note that the two may be related because OCB may affect: 1) the organizational, social, and psychological context for tasks and processes through enhancing coworker and managerial productivity; 2) the releasing of resources for more productive purposes by reducing the need for maintenance and the coordination of activities among team members

and groups; 3) the enhancement of the organization's ability to attract and retain top caliber employees; 4) the improvement of organizational stability, relationships with the environment, and acceptance of change; and 5) the creation of social capital.^[2,9]

Additionally, a body of research suggests that OCB is related to performance. However, the relationship between performance and certain forms of OCB, such as helping, appears to be stronger than the relationship with others, such as sportsmanship and civic virtue.^[2] Yet, OCB researchers have reasoned that due to the positive effects OCB may have for the manager and the organization and because managers may perceive OCB as a sign of commitment to the organization, managers are likely to repay employees who demonstrate higher levels of OCB with a higher rating on performance evaluations. OCB may not only affect the managers' evaluations of employees' performances, but their overall impressions of individuals. If the manager sees an employee exhibiting behavior he or she connects with a specific personality trait, the manager will likely consider that trait in the overall evaluation. Additionally, the more the employee conforms to a manager's vision of a good employee, the more likely positive behavior will be noticed and considered in evaluations.^[2] OCB, because it is not required, may appear especially impressive to the manager.^[2]

CONCLUSIONS

Despite the call for OCB to be utilized in the study of public administration, relatively little research has been conducted.^[10] There has been little cross-sector research on OCB but one study found higher levels of OCB in the public vs. the private sector.^[11] Studies undertaken in the public sector have shown that trust in supervisors mediated interactional justice and dimensions of OCB,^[12] job satisfaction is a predictor of altruism and compliance,^[13] contingent employees engage in OCB less than permanent employees,^[14] and organization-based self-esteem is positively related to OCB.^[15] Recent studies on OCB and the psychological contract framework have indicated perceived employer inducements were important predictors of OCB^[16] while an earlier study found perceived employer obligations explained variances in OCB better than perceived employer inducements.^[17] Despite the attention of a few scholars, the field of public administration needs to take a closer look at OCB, empirically and theoretically, to understand what insight OCB can bring to public administrators, especially in light of legal and political differences between work in the public and private sector.

The research exploring OCB in the workplace is still developing and has yet to reach undisputed

conclusions. Part of the challenge facing researchers is the multidimensional nature of OCB, which overlaps and creates confusion with a variety of similar concepts. In order for researchers to study OCB in a uniform manner, two significant hurdles need to be addressed. The first is researchers need to agree on a definitive definition of OCB that plainly distinguishes it from related concepts. The second difficulty is to draw a clear connection between OCB and organizational effectiveness. These obstacles are daunting, but if overcome, OCB could be an useful concept that would benefit research on both organizations and their citizens.

Organizational Commitment

Jong-In Yoon

Department of Political Science, University of Georgia, Athens, Georgia, U.S.A.

INTRODUCTION

How are employees linked to the organization for which they work (or to which they belong)? Such a question has been with us for a long time in academia as well as in real life. Early management literature discussed the issue of employee loyalty. For example, to Barnard,^[1] loyalty is a willingness of persons to contribute efforts to the cooperative system of the organization, which he believed is an essential condition of organization. However, the controversies over the origin, nature, and creation of loyalty continued into and through the 1960s. By the early 1970s the concept of loyalty began to be discussed under a new description called organizational commitment (OC). Generally, the concept of OC contains some elements found in the concept of loyalty, but several new elements are also noticeable.

ABOUT ORGANIZATIONAL COMMITMENT

OC is generally believed to represent *an individual and psychological bond between an employee and an organization*, which includes loyalty to and identification with an organization. OC has been a popular topic during the past three decades, and a series of meta-analyses provide a summary of that literature (e.g., Refs.^[2–4]). So, what makes OC attractive to scholars and practitioners? Briefly, gaining a greater understanding of the processes related to OC has implications for employees, organizations, and society as a whole.

Basic hypotheses argue that employee commitment produces personal benefits such as non-work and career satisfaction. People need to be committed to something, and the opposite of commitment is alienation, which is obviously unhealthy. In this sense, commitment is different from workaholicism. In addition, from the perspective of an organization, commitment is viewed as a fairly stable and reliable predictor of employee behaviors such as turnover, when compared to other attitudinal constructs such as job satisfaction. Organizations also value commitment, because it is typically believed to reduce withdrawal behaviors. Moreover, committed employees are more likely to be involved in extra-role behaviors such as creativeness

and innovativeness, which are also assumed to enhance organizational competitiveness.

From a larger perspective, society as a whole also benefits from OC, because it may lower rates of costly job movement and may enhance national productivity or work quality. Overall, empirical research thus far reports modest inverse relationships between OC and turnover, intention to leave, and absenteeism.

Recently, some cynics argue that the notion of OC has faded away in the welter of work environments such as megamergers, layoffs, and contracting-outs. They also recommend that employees not become too involved in their organizations but instead look out for themselves (or their families) and prepare themselves for employment in other organizations in the event of a layoff.

However, the study of OC is neither useless nor outdated. Employees are still much committed to their organizations, in contrast to the expectations of some cynics. One survey asked IT workers to estimate the percentage of their coworkers who were “extremely committed.” Respondents reported that about 70% of their coworkers were “extremely committed” to their organization.^[5] In addition, although organizations change, they do not disappear. Rather, as organizations become leaner and smarter, those who remain in the organization become more important. Once the “fat” is gone, the remaining employees represent the “brain and muscle” of the organization.^[8]

This item addresses several aspects of OC. First, the meaning of OC, that is, the definitions and measurements of OC, is examined; second, the literature pertaining to the determinants and consequences of OC is reviewed; third, remaining issues and future research tasks are also discussed.

MEANING OF COMMITMENT

Definitions and Measurements

Although OC is one of the topics widely researched in organizational behavior, empirical literature with regard to OC is somewhat confusing, because there are many definitions and measurements of OC. For example, Mowday, Porter, and Steers^[6] reported 10 divergent definitions of OC, which reflect no consensus. This is partly due to the fact that researchers from

various disciplines (e.g., economics, psychology, sociology) have ascribed their own meanings to the construct of OC. However, these diverse definitions also reflect controversies over the nature of OC.

To illustrate, Fig. 1 shows one of the current typologies of OC, which challenges the unitary concept of OC. The distinction between a “behavioral” commitment and an “attitudinal” commitment is common and long-standing in the literature of OC, while the distinction between affective, continuance, and normative commitment is rather recent.

A behavioral approach posits that employees are committed to a specific course of action (e.g., maintaining employment with an organization). In this approach, an individual is committed through behavior. The more explicit, irrevocable, and public an individual’s prior activity has been, the more stable subsequent behavior will be. The theory of side-bets also argues that OC develops as an individual accumulates side-bets in an organization, which involves something valuable to an individual (e.g., pension, social connections, ease in doing work). The threat of losing these side-bets commits the individual to the organization.

On the other hand, an attitudinal approach focuses on an individual’s psychological attachment that links an individual to an organization. The attitudinal approach has been a mainstream of OC research. The most widely recognized definition of attitudinal commitment comes from Porter, Steers, Mowday, and Boulian,^[7] who defined commitment as “*the relative strength of an individual’s identification with and involvement in a particular organization.*” They also conceive OC as a complex concept that can be parceled into at least three factors: 1) a strong belief in and acceptance of the organization’s goals and values; 2) a willingness to exert considerable effort on behalf of the organization; and 3) a strong desire to maintain membership in the organization. In addition, the Organizational Commitment Questionnaire (or OCQ) developed by Porter and his colleagues has been widely used. In a meta-analysis, 59% of the 174 studies reviewed relied on the OCQ.^[2] The OCQ consists of 15 statements, and subsequent studies have reported that it has satisfactory test-retest and internal consistency reliability, and also has acceptable levels of predictive, convergent, and discriminant validity.

Fig. 1 A current typology of OC. (From Ref.^[11] p. 232.)

Although distinct, neither attitudinal nor behavioral approaches to OC can claim superiority. For example, a behavior may cause the development of congruent attitudes, which in turn lead to further the behaviors and vice versa. Thus, the development of OC may rely on the subtle interplay of the two types of commitment.

Distinction with Other Related Constructs

The relations of OC to major constructs also support its relevance. First, OC differs from the concept of job satisfaction, which is a positive emotional state resulting from the appraisal of one’s job. Generally, job satisfaction reflects one’s response to specific aspects of one’s job (e.g., pay, promotion) or to one’s job as a whole, whereas OC as a construct reflects one’s general affective response to the organization as a whole. OC reflects a more stable attitude over time than job satisfaction, which reflects one’s immediate affective reactions to job facets and to day-to-day transitory events. In sum, OC is more evaluative and macro than job satisfaction, and it develops more slowly over time.

Second, OC also differs from job involvement, which is the degree of absorption employees experience in their jobs. Obviously, one primary distinction between the two is that job involvement describes employees’ attachments to their jobs, whereas OC describes employees’ attachments to their organizations. However, the two constructs seem to be associated with each other to the extent that an organization provides an employee with what is desired.

Third, occupational commitment (or career commitment, career salience, professional commitment) refers to an employee’s commitment to occupation (or career, profession). Although the early literature stressed the inherent conflict between organizational and professional commitments, those two commitments may not necessarily be incompatible.

In fact, although OC is distinguished from such constructs as those mentioned above, the moderate or high correlations between OC and other constructs hint at the potential “concept redundancy” between them. Concept redundancy exists when conceptual definitions do not prove mutually exclusive, or when the link between a concept and its measurement is less than perfect. More research efforts should be paid to examine the relationships between diverse forms of work commitment.

DEVELOPMENT OF ORGANIZATIONAL COMMITMENT

The literature of OC provides “a long laundry list” of variables associated with OC, directly or indirectly, but

the majority of empirical studies investigating the determinants and consequences of OC are correlational. Thus, although this article uses such terms as “determinants” and “consequences,” few of OC empirical studies have been designed in a way that fully justifies such terms.

Literally hundreds of studies have examined the relationships between OC and its determinants, but one common theme underlying the development of OC is the notion of *exchange* between employees and their organizations. Individuals come to organizations with certain needs, desires, and skills. Organizations satisfying those needs and desires may have more committed employees. The notion of exchange is valuable not only from a conceptual standpoint in understanding the development of OC, but also from a societal standpoint in understanding that commitment is not simply a means of managerial exploitation of employees.^[6] The following discussions are drawn mainly from previous reviews.

Personal Characteristics

Overall, age and tenure have positive, albeit weak, relations with OC, but the interpretation of those results is not unequivocal. Consider whether older workers are more committed to their organizations, or experience limited job alternatives and greater sunk costs. Alternatively, older employees might actually have more positive work experiences than younger employees. Then, work experience rather than age is a true factor. When it comes to tenure, employees might become strongly attached to their organizations as tenure increases. Or it might be due to the fact that, over time, those who do not have strong OC choose to leave the organization, and only those who develop strong OC remain among the long-tenured group.

In contrast to age and tenure, the effects of gender and education on OC are less consistent. Roughly, women tend to be more committed to an organization. One explanation is that women have to overcome more barriers to attain their organizational positions. Empirical findings generally report an inverse relationship between education and OC, because highly educated employees may have higher expectations that the organization is often unable to meet and may have more alternative job opportunities than less-educated employees.

OC is also related to such dispositional variables as achievement motivation, sense of competence, and other high-order needs. Employees might be more committed to the organization that meets their high-order needs such as a need for achievement. In addition, the perceived competence has shown a large positive correlation with OC across diverse work

samples, indicating that employees confident in their abilities and achievements have higher OC than those who are less confident. An alternative explanation is that competent employees can choose higher-quality organizations that inspire strong OC.

In sum, even if unclear, the correlations obtained thus far imply that personal differences should be taken into account in any model of OC.^[6] At this point, it is difficult to confirm that OC derives directly from demographic and dispositional variables. The possibility remains that the relations between personal characteristics and OC are moderated by other variables, e.g., organizational or work experience variables.

Organizational Characteristics

Relatively recent attention has gone to the influence of organizational characteristics (e.g., organizational size, decentralization, and formalization) on OC. Researchers have found that employees experiencing greater decentralization and greater formality of written rules are more likely to feel committed to their organizations than employees experiencing these factors to a lesser extent. With regard to organizational size, some report that larger organizations tend to be less personal and harder to identify with, while others argue that larger organizations may increase the chances of promotions and other forms of intrinsic and extrinsic benefits. No one knows. Possibly, stronger relations between organizational characteristics and OC would be observed if they were examined by using an organizational level of analysis instead of (as is usual) an individual level of analysis.^[8]

Work Experiences

The vast majority of determinants studied thus far fall into the broad category of work experiences, which encompass such variables as job scope, role ambiguity, supportiveness, fairness, and leadership styles. Most variables have been measured by employees' perceptions rather than objective assessment of those characteristics. Generally, jobs that are perceived more general, complex, challenging, or enriching, have been found to lead to higher levels of OC. In addition, empirical studies have found that OC is lower among employees who are not sure about their roles (role ambiguity), or who feel that their roles are incompatible (role conflict). Similarly, role overload has been found to be inversely related to OC.

Empirical research also reports that OC is positively associated with participation in decision making, leader consideration, and organizational supportiveness and fairness. Significant positive correlations have also been reported between perceived fairness of specific

policies (e.g., pay and strategic decision making) and OC. In addition, it appears that the relations between leaders, coworkers, and employees have an impact on OC. Although less consistent, group cohesiveness has been found to be positively related to OC. Commitment also has shown positive relations to such variables as leader consideration, leader communication, and participatory leadership. Compared to personal and structural variables, in general, work experience variables have shown stronger and more consistent associations with OC.

CONSEQUENCES OF ORGANIZATIONAL COMMITMENT

As one priority, the literature of OC has focused on such variables as withdrawal behaviors (attendance, lateness, turnover) and withdrawal intentions (intention to search for job alternatives, intention to leave), and performance. Given that OC refers to a psychological bond between an employee and the organization, OC is anticipated to be negatively associated with withdrawal intentions and behaviors. Meta-analytic evidence illustrates that OC correlates positively with attendance and negatively with lateness and turnover, although these effects were relatively weak. In fact, however, OC demonstrates much larger correlations with withdrawal intentions—intention to search for job alternatives and intention to leave. This suggests that the effect of OC on turnover may be indirect through its relationship to (or mediated by) intention to leave or intention to search for another job.

Ultimately, perhaps, OC research highlights performance, but findings are weak and mixed. Why? Commitment may influence job performance, but so might factors like technology and resources. Thus, perhaps, we should not expect a strong commitment–performance linkage.

However, some optimism about the OC–performance linkage also deserves notice. Primarily, perhaps, the reason inheres in the poor validity of performance ratings, because supervisors do not take performance ratings seriously. Second, the impact of OC on performance may appear most clearly in the performance indicators that reflect employee motivation, while being relatively unconstrained by other factors (e.g., ability, access to resources), for example, employee initiative or organizational citizenship behaviors. In a related sense, for OC to influence particular performance outcomes, employees must have adequate control over the outcomes in question (e.g., cost controls). Third, most studies have examined the relations between OC and performance indicators at the individual level of analysis. Relevantly, studies adopting group or organization-level analyses have shown

stronger correlations between commitment and some performance variables. This suggests that OC may contribute to organization-level performance through ways other than individual-level performance. For example, some studies have found significant positive correlations between OC and extra-role behaviors, which go beyond and above one's job description.

CONCLUSION AND REMAINING ISSUES

The concept of OC has received intense attention during the past decades, and it will remain with us in the future. Gaining a greater understanding of how OC develops and evolves over time has significant implications for individuals and organizations, as long as organizations and employees exist. Even now, we know a great deal about the origin, nature, and consequences of OC. Clearly, much also remains unknown.

Definitions and Measurement of OC

Most obviously, continuous refinements of definitions and measurements are necessary. Recently, as noted, differentiating two or more dimensions of OC has received attention, and opinion converges on the view that *commitment is a multidimensional construct, not a unidimensional one* (see Fig. 1). They suggest that employees' dedication to an organization has a three-fold involvement: calculative (based on material rewards or side bets), affective (based on affiliation), and normative (based on obligation or value congruence).

As a further useful complication, a traditional view of commitment has come more frequently to be seen as an attachment to the organization as a whole. Emerging multifacets (or foci) of commitment involve simultaneously organization, division, coworkers, projects, or the public.

Although they need further empirical support, those two approaches—multidimensional and multifacet commitment approaches—have several advantages over traditional views of OC. Thus, multidimensional approaches open the possibility that we can understand more clearly the nature and origin of commitment. This is useful, in particular, for OC research in the public sector. For instance, the overall low OC reported among public employees (e.g., Ref.^[9]) may be largely due to low calculative commitment, regardless of high normative commitment. In particular, the concept of normative commitment may help explain any intrinsic motivation of public sector employees. This line of argument challenges the prevailing assumption in public sector HRM practices that public

employees are fundamentally self-interested and material rewards-oriented.

Relatedly, multifacet approaches fit well with current flexible and lateral organizational forms as well as with emphases on teams and groups within organizations. By investigating the foci of employee commitment, we might understand the development and consequences of OC more precisely and identify potential conflicts among multiple commitments within an organization. If anything, indeed, multifoci approaches appear to be more adequate for the study of OC in public organizations. The literature in public administration suggests that public managers have multiple masters, and that multiple constituencies affect public policies.

Model Construction and Testing

Most OC studies have been correlational and cross-sectional in design and thus have sharp limitations on causal inference, and insufficiently relate to psychological processes involved in the development and consequences of OC. Recently, causal models of commitment have received research attention, using OC as an endogenous or a mediating variable. OC has often been included as a mediator in such causal models, which link various personal characteristics and work experiences to job performance or turnover. A greater use of theory-based causal modeling techniques seems appropriate.

More longitudinal studies that investigate what factors are most important to employees at various career stages are also needed, given that OC seems a process that begins before an employee enters an organization and unfolds over time. In particular, longitudinal studies combined with multidimensional and multifacet commitment approaches may shed light on the change of the patterns (bases and foci) of commitments through an employee's career stages. In turn, this will guide organizational interventions or policies aimed at managing commitment patterns and, subsequently, their influences on employees' behavior.

Diversification of Research Methodologies

Common-method bias, a well-known problem in organizational behavior research, limits survey design in OC research. This bias occurs when measures of two or more variables are collected from the same respondents and methods, and the attempt is made to interpret any correlations among them. This bias can have extreme effects on the probability of finding significant results, even when there is no true relationship among variables. Another related concern is the social desirability bias, which occurs because questionnaire

items may prompt responses that present the person in a favorable light. Social desirability response may lead to bias in responses to questionnaires.

The OC researcher has defenses. Several research designs help resolve those problems—multitrait/multimethod approach, statistical control through partial correlation, and elimination of social desirability by using social desirability scales.

Negative Impacts of OC

So far, OC has been recognized as a positive factor for individual, organizations, and society. However, some observers raise the possibility of potential negative impacts of high levels of OC, among which are less creativity, resistance to change, stress, overconformity, and even a willingness to engage in corporate crimes. This possibility suggests that the relations between commitment and desirable outcomes adopt an inverted U curve, implying that over a certain point, high OC leads to be detrimental to individuals and organizations. Generally, the potential negative effects of OC get little attention.

Cross-Organizational and Cross-Cultural Studies

A large amount of most studies on OC involves samples from a single organization, and correlates employees' perceptions of organizational features and individual OC levels. Obviously, this generates problems, such as the restriction of variance and, subsequently, restriction of the true magnitudes of correlations between variables. Employee samples from a wide variety of organizations thus have a high priority in future research.

In a related vein, management theories and generalizations developed in one setting may not be automatically applicable to other cultures. Consider two conflicting views in the literature. A cultural determinist standpoint proposes that concepts, theories, and practices developed in one culture cannot be applied universally. In contrast, the theory of societal convergence argues that technology rather than culture plays a key role in determining worker attitudes, and thus, workers everywhere evolve similar patterns of work attitudes. This orientation suggests that work attitudes in other cultural settings may resemble those of the United States.

Research on OC outside of the United States is still at its early stage. Articles examining OC from a cross-cultural perspective have just recently begun to appear in academic journals. For example, through a search for the period from the late sixties to 1993, Randall^[10] found only 27 empirical studies investigating OC in

cross-cultural settings. To make matters worse, even most of those cross-cultural studies on OC are heavily tilted toward a few countries, such as Canada, Japan, and Israel. Obviously, more cross-cultural studies are needed.

Organizational Culture

Craig Lundberg

School of Hotel Administration, Cornell University, Ithaca, New York, U.S.A.

INTRODUCTION

The phenomena referred to as organizational culture, after early charges of mysticism and faddism, has become both popular and legitimate, and has a growing literature. Regardless of its evolving sophistication and contemporary stature as a field of study by scholars and as a source of inspiration for practitioners, organizational culture continues to be sidetracked by numerous, vigorously debated questions. Is culture something organizations are? Is organizational culture an independent or a dependent variable? For an organization, is there one culture, a set of subcultures, or both? Can organizational culture be known through objective assessment or only through interpretation or inference? Is each organizational culture unique, or does each have features in common that permit comparative analysis? Behind many, if not most, of the debated questions is a more fundamental, double-barreled one: is organizational culture amenable to change? If so, can organizational culture change be managed? To date, responses have been polarized. Some answer that cultures are changeable and of course they can be managed, whereas others respond that cultures have a life of their own that cannot be planned for or intervened with. The stance taken here is that such responses are overstated, glossing both the phenomena and our thinking about it.

The significance of organizational culture—that is, why it has drawn the attention of scholars and practitioners alike—is probably because it raises to consciousness features of organizations and the behavior of their members heretofore relatively ignored. Cultures after all are essentially about meanings, deep, symbolic, and otherwise, and meanings are always emotionally laden—two features largely taboo in organizational life. Cultures also serve as a major source of identity, provide nuanced behavioral guidance, reduce uncertainty, permit claims and justifications, and are of significance to people joined together in pursuit of common goals. Even the ways of understanding organizational cultures have utility. For example, we are counseled to look closely at the details of cultural specifics and to stand back and see cultures as wholes—to alternate careful description and cautious interpretation—ways of knowing that are both insightful and have built-in correctives. In a relatively random, often

ambiguous, and largely unknowable world, it can be argued that cultures are essential for collective activity and human health, development, and survival. In a world of change—large and small, swift and slow, but ubiquitous and continuous—the influence of organizational cultures on change, and the influence of change on cultures, merits close attention.

Regardless of the reasons for engaging in culture work, consequences are inevitable. As already mentioned, performing culture work (i.e., surfacing) can enhance socialization and team development. Also, as members become more aware of their organization's culture, this awareness contributes to the body of information on which everyday decisions and actions are based. Such cultural awareness often leads to subtle as well as intentional self-correcting behaviors—reinforcing patterned behaviors seemingly congruent with the culture and altering those that are not. Culture work can and usually does prepare members for deliberate organizational diagnosis and redesign of formal structures, systems, and processes (i.e., knowing what is culturally feasible). Thus, when formal changes are proposed (e.g., goal setting, and strategic/tactical planning), culture work assesses if it is consistent with the culture. Sometimes, probably rarely, culture surfacing and assessment may mobilize the concern and energy that leads to a new vision for a desired culture and efforts to craft it.

To argue, as is the intent of this article, that some aspects of cultures, under some circumstances, are amenable to intentional management change suggests that we go beyond the contemporary culture debates, as well as the piece-meal quality of the contemporary culture literature, to attempt to see more and see differently. Thus, this article outlines the assumptions and common understanding of the phenomena of culture, as well as culture's functions and significance, and offers a framework for cultural understanding.

WHAT IS ORGANIZATIONAL CULTURE?

The phenomena referred to as organizational culture, after early charges of mysticism and faddism, has become both popular and legitimate (e.g., Ref.^[1]). Although the construct of culture has been with us for a long time and has been enormously elaborated

(e.g., Ref.^[2]), the focus and the field known as organizational culture is of fairly recent origin.^[3] Although the phenomena were emphasized by a few early writers on organizations, “culture,” organizationally conceived, pushes us into territory left insufficiently explored by ideas that came before it. Group norms seemed sufficient to explain such phenomenon as why participants of off-site training reverted to their former behaviors and attitudes once they returned to their work setting. Organizational climate, although lending itself to measurement and association with many variables of importance, like norms, ultimately did not allow an explanation of the deeper casual aspects of how organizations function. By the 1960s, a growing emphasis on whole organizations began and concepts such as “system” were evoked to describe the patterns of norms, attitudes, and values organizationwide. Needed, moreover, were explanations for variations in climate, norms, and organizational behavior, and levels of stability in group and organizational behavior.^[4,5]

Although the phenomena of organizational culture have always existed, its popularity only began in the 1980s. This popularity undoubtedly began with Deal and Kennedy's^[6] *Corporate Cultures* and continued with Davis^[7] in *Managing Corporate Culture*. However, the literature has grown swiftly. A succession of more carefully conceived and empirically based efforts has provided elaboration of what organizational culture is, how it may be studied, its relationship to strategy, structure, and management practices, as well as several cautions (e.g., Refs.^[8–11]).

As with any growing field of study, however, the concept of organizational culture has many definitions. This is partly because culture is one of the most familiar things in our experience—we have grown up in a culture, intuitively know it and use it every day—and this excessive familiarity makes culture a difficult phenomenon on which to focus, much less to crisply conceptualize. Although definitions abound, almost all of them contain one or more central ideas such as values, shared meanings, assumptions, and beliefs. All definitions, however, subsume a distinctive set of assumptions about organizations and human behavior:

- Most of what happens in organizations is substantially more uncertain or ambiguous than in prevailing theories.^a
- Ambiguity and uncertainty undermine common, traditional approaches to analysis, problem solving, coordination, and control.

^aPrevailing theories assume that organizations are designed, purposive, more or less formalized systems consistent with a paradigm of intentionality where there is an unquestioned presumption of logic. (Ref.^[12].) and a compelling climate of rationality. (Ref.^[13].)

- People naturally create and perpetuate symbols of all types to combat chaos, provide direction, increase predictability, resolve confusion, and the like.

A distillation of the definitions and themes in the literature provides useful conceptual understanding of the phenomenon. There is a growing convergence that culture may be understood as a layered phenomenon, that it is composed of two or three interrelated levels of meanings from those relatively observable to those mostly invisible. Behind the many definitions, conceptual frameworks, and points of view about organizational culture, several widespread understandings of the phenomena can be discerned:

- It is a shared, common frame of reference (i.e., it is largely taken for granted and is shared by some significant portion of members).
- It is acquired and governs (i.e., it is socially learned and transmitted by members and provides them with rules for their organizational behavior).
- It endures over time (i.e., it can be found in any fairly stable social unit of any size, as long as it has some history).
- It is symbolic (i.e., it is manifested in observables such as language, behavior, and things to which are attributed meanings).
- It is at its core typically invisible and determinant (i.e., it is ultimately comprised of a configuration of deeply buried values and assumptions).
- It is modifiable, but not easily so.

Popular accounts of organizational culture emphasize the exotic and uncommon—heros, unusual labels, dramatic stories, peculiar ceremonies, and special events (e.g., the pink Cadillacs of Mary Kay Cosmetics, R and D skunk works, a chief executive officer “pitching in” on the production floor, the garage origins of a computer firm). Although such colorful anecdotes easily capture our attention, it is easy to miss their point; namely, that they are symbolic and their meaning is found in how they relate to a configuration of deeper elements.

If we look closely at the many definitions, common themes, conceptual schemes, and perspectives for discovering organizational culture, we can notice that there are essentially just two components: observable patterned behavior such as norms, language, customs, etc., and inferred cognitive-emotional ideas such as assumptions, beliefs, and other shared meanings. We further notice that these two components vary by level of generality or scope, from the specific to the philosophical, and are linked. The ideas serve as frames that cue the observed activity: “A cue in a frame is what makes sense, not the cue alone or the frame alone.”^[14] Meaning is therefore relational. Organizational culture

is thus understood as an organized set of ideas that draws attention to the phenomenon of observable patterned behavior (activities and events) and gives them meaning. It is the nature of the relationship between culture ideas and their phenomenon that is crucial.

The significance of organizational culture—that is, why it has drawn the attention of scholars and practitioners alike—is probably because it raises to consciousness features of organizations and the behavior of their members heretofore relatively ignored. Cultures after all are essentially about meanings—deep, symbolic, and otherwise—and meanings are always emotionally laden. These two features are largely taboo in organizational life.

What does organizational culture contribute to an organization and its members? Organizations share common issues and tasks—from survival in their external environments to managing their internal affairs, from handling crises to inculcating new members, from dealing with growth or decline to maintaining morale, from measuring performance to renewing product/service offerings. Organizational culture in one sense provides the organization’s solutions to these issues and tasks. What has been found to have consistently worked over time is symbolically expressed and maintained through patterned behaviors and devices as guides to future actions. Culture, therefore, is what is taught and reinforced, typically unconsciously, to members as the proper way to perceive, think, feel, and act in relation to the organization’s ongoing and recurring issues and fundamental tasks. As such, culture becomes both the source and the vehicle of organizational meanings.

Through its meaning-infused symbols and patterned activities, organizational culture provides much that is invaluable to organizations and members. It is, as mentioned, that which defines the uniqueness of the organization and serves as an organizational identity, or the meaning of who we are collectively. It also provides that which enables members to create their organizational identity. Organizational culture is also the basis for order, direction, and coherence—the meanings of where we are going and how we are related.

Culture, as central meanings, provides the rationale and supportive reasoning for an organization’s mission, strategy, and policy—in fact, for all required activities and responsibilities. It says, in effect, what we are jointly about and why we bother doing it. As cultural meanings are acquired by members they serve to mobilize, guide, and control human energy. Members learn what is generally expected of them as members—their understandings of what is appropriate and inappropriate behavior. Organizational culture as meaning also fills the void of uncertainty, too, and is therefore the primary source of anxiety reduction for members and others (e.g., the organization’s

stakeholders). Organizational culture is functional in that it provides meaningful response to the sorts of questions that pervade human existence: Who are we? What are we about? How should we behave?

LEVELS OF MEANING APPROACH

The investigation and understanding of organizational cultures is formed by a “levels of meaning” approach as outlined in Table 1. Let us briefly examine this framework. At the heart of any ongoing organization is a configuration of organization-specific *values and assumptions* (and associated ideology) that constitute its essential character. This core serves as the set of premises or precepts that strongly affect the vast majority of organizational thought and action. Values are the collective sense of what should be striven for or avoided, and the real ideals and standards and sins of the organization. Assumptions are the shared premises on which the dominant coalition bases its world views. Assumptions, therefore, refer to very basic things: the nature of human relationships, the nature of truth and time, the nature of human activity, and whether certain classes of people should be given preferential treatment. A central value and assumption always has to do with change, whether it is really possible or desirable, as well as who should initiate and manage it. This core level of meaning is essentially “taken for granted” and, to know it, we infer its components from other, more visible things.

A middle level of meaning comprises organization-specific *strategic beliefs*. Strategic beliefs refer not to the long-range plans or strategic pronouncements of organizational spokespersons, but rather to the fundamental “oughts” in the minds of the influential organizational leaders. There are four basic types of strategic beliefs.^[15]

- 1. Beliefs about strategic vision (i.e., what the organization can become and do, and what it will not attempt)

Table 1 “Levels of meaning” framework for understanding organizational culture

Manifest level

2. Beliefs about capital market expectations (i.e., convictions about what is necessary to keep lenders and investors satisfied)
3. Beliefs about product–market competition (i.e., understanding how and why the organization can succeed in its task environment and industry)
4. Beliefs about internal managing (i.e., the appropriate operating practices that support the other beliefs)

Strategic beliefs reflect, on the one hand, the cultural core and, on the other hand, actively condition the most surface or visible level.

Every organization or significant subpart that has some history will have developed a set of organization-specific *manifest elements*, which are relatively visible in that some careful, systematic listening and observing will reveal them. There are:

1. Symbolic artifacts (i.e., meaning-infused objects)
2. Unique language elements—a unique vocabulary (jargon), slang (argot), and sayings and slogans—and their non-verbal counterparts
3. Organizational stories about significant persons and events—some true and some elaborated, such as fictional myths and heroic sagas
4. Repeated social events—rituals that reaffirm and mark what is important, and ceremonies that signify key transitions or enable something deemed important to happen more easily
5. Patterned conduct—the norms, conventions, and customs that inform members about appropriate behavior and the preferred style of relating

Collectively, these manifest elements predispose members to experience organizational events, activities, and things in certain ways, to identify problems in similar ways, to perform within acceptable limits, and to strive toward common purposes. Experiencing the manifest culture, members over time come to acquire and share a unique common psychology familiarly understood as organizational “know-how.”

Four additional points require emphasis. The first point is the fallacy of believing that there is just one organizational culture. Although most organizations do have a more or less well-developed “umbrella” culture, it is also common that most organizational subsystems also have cultures (e.g., divisions or departments, major layers of the organization), as do the major occupations of the organization.^[16] Also, there is always the question of congruence among subsystem cultures, and between them and the umbrella culture.

The second point to emphasize builds on the first. Organizational and subsystem cultures may vary considerably along a continuum of intraculture clarity and consensus. Some cultures, regardless of size, have

meanings that are consistent and agreed upon (i.e., so-called “strong cultures”). Other cultures may hold differentiated and multiple meanings. Martin^[17] suggested the following cultural alternatives: “integration” (where the meanings of the dominant coalition are shared organizationwide), “differentiation” (where meanings overlap, collide, or coexist across subsystems), and “fragmentation” (where meanings are usually multiple and more ambiguous across all units of analysis from person to organization). The point here is not to assume either an intra- or intersystem consensus of meaning.

The third point to emphasize is that the examination of levels of meaning and the identification of meanings is quite difficult because such interpretive sense making always reflects the cultural allegiances of the investigators.

Last, organizational culture research tends to appear in one or the other of two major pairs of perspectives, the functionalist and the interpretive,^[18] and either the insider (emic) or outsider (etic) perspective^[19]—each important and useful.

The early debates about whether organizational culture can be managed and whether there is a single best perspective have largely been settled. Today, few would argue either that culture is usefully viewed as an independent variable (and hence is not manageable) or that culture is most usefully viewed as an objective phenomena (social constructivism now predominates). The continuing debates revolve around preferences for studying organizational culture (i.e., whether up close, such as ethnographically, or from afar, such as with questionnaire surveys) and preferences for describing cultural meanings (i.e., as contextually unique or in terms of cross cultural generalizations).

CONCLUSION

As we enter into the twenty-first century, organizational culture work needs to proceed on at least two fronts. The first front is conceptual. For example, organizational culture needs to be clearly differentiated from several closely associated constructs, such as climate and identity,^[17] elaborated in terms of previously underdiscussed components, such as emotion and time, and clarified in terms of encompassing cultural units, such as national and industry cultures, and cultural boundaries. The second front is empirical. Organizational culture needs to be studied longitudinally for antecedents and consequences in emerging contexts, such as multinational organizations spatially dispersed and virtual organizations, and whether it leads or follows organizational strategy and structure, and organizational transformation. Organizational culture, however, is the nexus of a symbolic meaning-centered paradigm that usefully

contributes to our thinking about the governance of postbureaucratic organizations.

INTRODUCTION

Recognizing that “the President needs help,” Franklin D. Roosevelt appointed the Committee on Administrative Management, charged to make recommendations for improving the efficiency of the Presidents’ office. The Committee was popularly known as The Brownlow Committee, named after its chairman, Professor Louis Brownlow, who had been prominent in developing city management as a profession. The two other members of the Committee were Charles Miriam of the University of Chicago, and Luther Gulick of Columbia University and the Institute of Public Administration in New York City.

They subsequently shared their basic principles with the reading public. Gulick joined with Colonel Lindal Urwick and published in 1937, as a report to the Committee, *The Papers on the Science of Administration*.

IMPORTANCE OF THE “PAPERS”

The *Papers on the Science of Administration* is a collection of 11 essays or “papers” on how to more artfully manage modern organizations. They set forth the thesis that certain “principles” govern in effective management, and that by defining and living in harmony with those principles, managerial effectiveness and organizational productivity are increased. These principles are found in public and private settings. In explaining this phenomenon, Urwick wrote: “there are principles which can be arrived at inductively from the study of human experience of organization, which should govern arrangements for human association of any kind. These principles can be studied as a technical question, irrespective of the purpose of the enterprise, the personnel composing it, or any constitutional, political, or social theory underlying its creation.”^[1] These papers and this article are important, because they defined a theory of management that became

the focal point in the debate over the shape of public administration for years to come.

The papers were written in an era when Frederick W. Taylor’s *Principles of Scientific Management*—which argued that by applying scientific principles to management, the “one best way” of doing things might be discovered—had captured the imagination and practice of many managers in the public and private sectors.^[2] The *Papers on the Science of Administration* marked what many have called the “high noon of orthodoxy” in the practice of public administration, and it was recognized as the clearest exposition of its principles. Gulick asked the question, “What is the work of the chief executive?” and responded by asserting “The answer is POSDCORB,” a pithy anagram which summarized the executive’s role of Planning, Organizing, Staffing, Directing, Coordinating, Reporting, and Budgeting.^[2] At the time of their publication, the nation was pulling out of the great depression and was soon to be engulfed in World War II. POSDCORB gave government managers a system to approach the planning, organizing, staffing, and so on central to managing these great crises, which was done so well that Newland identified this period as “the golden age” of American public administration.^[3]

POSDCORB was also important because it began to pull together the intellectual fabric for the study of public administration and provide a common view point for the academics “who founded such key institutions as the Public Administration Clearing House (1930), the American Society for Public Administration (1939), and the Public Administration Review (1940), which significantly advanced research and teaching agendas for the field. POSDCORB further provided a cohesive and comprehensive academic rationale for setting up graduate programs advancing research as well as its applications” at federal, state, and local levels of government.^[4] Thus, it was that the “principles of administration” played a signal role in the growth and development of the field of public administration.

THE DEBATE OVER PRINCIPLES

Perhaps the most important impact of POSDCORB and the *Papers on the Science of Administration* was in the debate they triggered, which further defined the field of public administration. Following World War II, Simon, Dahl, and Waldo, in particular, argued that the principles identified by Gulick and Urwick were not principles at all, but merely “proverbs,” buffeted by all the subjective nuances of perception, values, and bias inherent in the human condition.^[5–7] Simon, in particular, argued that for every “principle” of administration an opposing “principle” existed, some of which were mutually contradictory, and that therefore, the idea of “principles” was moot.^[8] Still, the *Papers on the Science of Administration* are important for the impact they have had in shaping the field of public administration, in focusing attention on the role of upper-level management in government and in the insights proffered by individual authors of the articles.

Parental Rights and Obligations

Michael W. Austin

*Department of Philosophy and Religion, Eastern Kentucky University,
Richmond, Kentucky, U.S.A.*

INTRODUCTION

In the past 30 years, advances in reproductive technology and social change have led to increased reflection on the nature of parenthood. Because of these advances, many people who in the past would not have been able to gain access to the joys and challenges of parenthood can now gain such joys. These technologies and their implications also raise important moral and legal questions about the nature of the parent–child relationship. How should we think about being a parent? If parents have rights, how extensive are they? What obligations do parents have to their children? Should we require prospective parents to be licensed before we allow them to procreate and raise children? These are some of the theoretically and practically important questions related to the parent–child relationship.

PARENTHOOD: ABSOLUTISM AND LIBERATIONISM

Historically, some have proposed an absolutist view of the rights and obligations of parents.^[1] Absolutists hold that parents have complete and final authority over their children and over decisions that have an impact on them. Some absolutists have even argued that parents hold the power of life and death over their children. An absolutist view of parenthood often arises from the belief that children are somehow the property of their parents, and as property-owners have control of their property, parents, as such, have control over their children. One reason that absolutists offer for believing that parents have this level of authority is that such authority discourages vice in children and encourages them to develop respect for the laws of the state. Children are to learn obedience in the family, so that they can learn obedience in society, and be subject to the laws of the commonwealth. While absolutism is no longer a widely-held view among scholars, it is still the case that many people conceive of themselves as having near absolute control over their children.

Many justifications have been offered for the paternalistic treatment of children by their parents and society. For example, some hold that children are the property of their parents, as noted earlier. Others maintain that parents have authority over their children simply because they created them. Lastly, some argue that it is because children are incapable of taking care of themselves that parents and society can treat children paternalistically.

The children's liberationist rejects all of these arguments, and liberationism contrasts sharply with absolutism. Some liberationists argue that children should be able to do, without permission, whatever adults are allowed to do.^[2] Supporters of liberationism argue that children should have the same moral and legal status as adults, and so should be granted the same rights and freedoms possessed by any other member of society, such as the right to vote, the right to self-determination, the right to design their own education, the right to forgo education altogether, the right to sexual freedom, the right to alternative home environments, and the right to select guardians other than their parents.

The extreme absolutist holds that children essentially have no rights, whereas the extreme liberationist holds that children have all the rights that adults possess. There is much logical space between these two positions, which allows for both parents and children to be possessors of rights, *qua* parents and children. It is the case, however, that the greater the extent of the rights that children possess, there will be a corresponding reduction in the extent of the rights that parents possess, *qua* parents.

PARENTS AND CHILDREN: SOME RELIGIOUS APPROACHES

While it must be emphasized that it can be unclear what a particular religion teaches about the rights and obligations of parents, given the diversity of viewpoints within different religious traditions, it is the case that adherents to many of the major world religions address many of the moral and legal issues relevant to the parent–child relationship. For example, the

halakhah, i.e., the Jewish law, regulates the parent–child relationship via a system of mutual obligations that devolve on parents and children.^[3] The obligation to provide support for children falls solely on the father under the halakhah. Fathers have authority over their households, but are also obligated to provide for a child's daily needs, to educate the child in the ways of Judaism, and to teach male children a trade, among other duties. Also, fathers do not have the right to forfeit their parental obligations, whereas mothers may do so, in which case the children become wards of the community. In situations of divorce, parents are obligated to retain custody of their children. This obligation is grounded in the child's welfare, which generates a right of the child to be cared for by his or her parents. This emphasis on the moral and legal claims of children that arise out of their vulnerability is a widely-held view in both religious and nonreligious conceptions of the rights and obligations of parents.

Christian teaching with respect to the parent–child relationship is also diverse. Jean Bodin's absolutist view was grounded in his understanding of divine law—he believed that God granted absolute authority to parents over their children. Of course, many Christian thinkers agree that parental authority is derived from or modeled upon the authority that God has over humanity, but reject absolutist views of the extent of parental authority. Both Saint Augustine and Saint Thomas Aquinas wrote on the family, basing their views on Christian considerations, and Aquinas is quite clear in his rejection of absolutism.^[4] Augustine holds that parents have responsibilities concerning their children. Parents should tend to the welfare of their children, but not seek to satisfy all of the wishes of their offspring. Children need to learn discipline from their parents, and to learn religious faith from them. Aquinas sees parents as superiors, in the sense that they are to supervise and instruct their children. For Aquinas, parents do have distinct parental rights, but these rights are not absolute, because children also possess rights owing to the fact that they are individual human beings who as such are objects of justice. The rights of parents are constrained by the obligations of parents to educate their children in the physical, mental, moral, and religious realms, and to provide for their daily needs.

In many non-Muslim cultures, the common understanding of a Muslim family ethic includes the absolute (or nearly so) authority of men, as husbands and fathers, over their households. While there is of course oppression of women and children in the name of Islam, this is true of other faiths as well. Some Islamic teachers emphasize the complementarity of men and women.^[5] By nature, it is believed, men

are physically stronger than women, and women are superior to men in their capacities for love and affection. Given this, the duty of safeguarding the family falls upon the man, whereas the duties of childrearing fall upon the woman. If families live according to this natural order, then all will experience satisfaction in family life. Of course, there are Muslims who disagree with the complementarity view, as well as others who would emphasize egalitarian considerations when describing the moral aspects of Islamic family life.^[6]

PARENTHOOD AND PUBLIC POLICY

The ubiquitous nature of cases of child abuse and neglect raises important questions for public policy as it relates to the family. Consider the case of Tanner Dowler. In February of 2004, Joseph Dowler was sentenced in Boulder Colorado District Court to 60 years in prison for child abuse leading to the death of his infant son, Tanner.^[7] In his nine weeks of life, Tanner Dowler suffered horrific injuries. Tanner endured 11 broken ribs, fractures in every limb, and oxygen deprivation that led to severe brain damage. He also suffered second-degree burns on the soles of his feet. At the sentencing hearing, Boulder District Attorney Mary Keenan read a statement from Tanner's perspective, saying that "I will never get my first tooth, sit up alone, crawl, or take my first step. I will never get to learn that neglect and rejection and fear and pain are not the way other people live their lives."

What can be done to prevent such abuses? One answer that has been proposed by Hugh LaFollette^[8] is that the state should legally require people to obtain a parenting license before they are allowed to raise a child. This sort of program would be aimed at preventing people like Joseph Dowler from having custody of a child, and so it would seek to prevent the suffering and death of children that occurs because of their parents. Children are among the most vulnerable among us, and so their vulnerability could demand protection from harm via the legal system when parents and other caretakers fail to fulfill their responsibilities. LaFollette's claim is that we should require parental licenses to prevent such failures from occurring in the first place.

LaFollette argues that if an activity is potentially harmful to others and requires a certain level of competence, which can be demonstrated via a moderately reliable test, then it should be regulated. For example, we require that physicians obtain medical licenses from the state to ensure their competency owing to the potential harm to citizens from medical malpractice. To drive an automobile, a level of

competence must be demonstrated because of the potential harm to others that can be done by incompetent drivers. Crucial to the argument in favor of licensing parents is that parenting shares these features with other activities for which we require licenses: It is potentially quite harmful and requires a certain level of demonstrable competence.

Parents can harm their children through abuse, neglect, and lack of love or respect. The results are physical and psychological damage, leading to adults who are neither well adjusted nor happy, and this often leads to cyclical patterns of abuse. Additionally, many people lack the competency required to parent children in an adequate way, owing to factors such as an unsuitable temperament, a lack of knowledge, a lack of energy, or instability. If the state requires that parents be licensed, then those who lack the competency required to be a parent and are therefore likely to harm their children in the ways described earlier would be prevented from doing so. Those who fail to obtain a parental license and yet bear a child would face having that child removed from home and given to qualified adoptive parents.

If we deny that parental licensing is justified, then, by parity of reasoning, we have no grounds to require licensing for physicians or automobile drivers, given that we require licenses for those who engage in these activities because they are potentially harmful and require a level of demonstrable competence. Moreover, we require that adoptive parents demonstrate a level of competence before being allowed to adopt a child. LaFollette concludes that a state program for licensing parents is desirable, justifiable, and feasible. This proposal is of course very controversial, insofar as the restrictions it places on those who may raise children are more stringent than those currently in operation.

Parents: Owners or Stewards?

How should parents conceive of themselves? Are they owners of their children, or stewards of them? To contemporary ears, applying the term “ownership” to the parent–child relationship can be morally problematic. William Irvine^[9] has developed a stewardship conception of parenthood that sharply contrasts with the ownership model. Irvine’s view is that parents should see themselves as trustees, or stewards, of their children’s lives.

To clarify the concept of stewardship, imagine that your neighbor is on a trip, and asks you to take care of his lawn while he is away. During the time he is away, you are a steward of your neighbor’s lawn. You mow it, water it, and seek to care for it as needed. Similarly, says Irvine, parents should see

themselves as stewards of their children. A parent can see himself/herself as caring for the body and mind of his/her child and acts as if the adult human person whom the child will become is away on a trip, a trip she will return from in approximately 20 years. At that time, the parent’s stewardship is finally and fully transferred over to the child, and the child who is now able to govern his or her own life is free to exercise control over that life. The steward-parent focuses his or her parenting on the child and the needs of the child, and is willing to sacrifice for the good of the child.

One could agree with this, but still hold that parents have moral and legal claims as well, given the goods that parenting makes possible, such as love, intimacy, and meaning in life. These goods might only be pursuable in the private sphere. So, the right to privacy also would cover family life, giving parents the right to rear their children based not only on the welfare of those children but also on the possibility for the satisfaction of desires for love, intimacy, and meaning on the part of the parents.

CONCLUSIONS

The parent–child relationship is one of the most significant relationships that human beings experience, as it can provide a deep sense of well being, intimacy, and love in the lives of both parents and children. Moreover, the impact of the quality of family life on civic life is great. Cycles of crime and violence are often perpetuated via families. So, parents, children, and the state have interests in play with regard to family life. While no consensus has been reached on the existence and extent of the rights of parents, or on the nature of parental obligations, these are crucial issues that merit further attention.

Participatory Policy Analysis

Virginia Eubanks

*Department of Women's Studies, University at Albany, State University of New York,
Albany, New York, U.S.A.*

INTRODUCTION

Participatory policy analysis (PPA) is a set of techniques, gaining popularity in the professional literature and practice, for expanding the range of actors involved in public decision making through deliberative dialogue. PPA arose from two sources: the new social movements of the 1960s and 1970s and recent critiques of “positivist” policy making. Scholars and advocates of more participatory approaches argue that PPA can help governmental bodies make better decisions, resolve intractable issues, empower and engage citizens, and promote justice and equity. Nevertheless, PPA has been subject to intense scrutiny and criticism, particularly in the international development community. Postpositivist critiques of policy making have not always resulted in convincing postpositivist methods or analytical instruments, and concerns about the wide uptake of PPA have taken several forms. These include lack of attention to social structure, implication in devolution and neoliberalism, and subjugation disguised as empowerment. This article discusses three examples of PPA in action. Examples of PPA are now fairly common in the professional literature, so these examples are neither exhaustive nor representative but do serve as an indicator of the breadth of current practice.

POSTPOSITIVISM AND POLICY ANALYSIS

In recent years, a “postpositivist” or “postempiricist” critique of traditional policy analysis has gained currency among policy makers, scholars, and activists.^[1–7] This point of view argues that positivist approaches to decision making—based on highly specialized, quantitative, instrumental, and “rational” processes derived largely from economics—have historically dominated the professional practice of the policy sciences at the expense of more democratic considerations.^[8] Positivist approaches to policy analysis, critics argue, tend to privilege elite forms of knowledge, discount stakeholders most affected by policy outcomes, perpetuate a false fact/value dichotomy, and marginalize policy analysis by narrowly conscribing the stages in the policy process at which analysis is

deemed appropriate. As such, technocratic policy analysis (and the instrumental rationality that underpins it) “destroys the more congenial, spontaneous, egalitarian and intrinsically meaningful aspects of human association...is antidemocratic...represses individuals...is ineffective when confronted with complex social problems...makes effective and appropriate policy analysis impossible...[and is based in] inappropriate and unfruitful social science instruments and methods.”^[3] These instrumental processes result, as critics note, in elite-oriented policy analysis, systemic and power-laden distortions of communication between analysts and their clients, and declining democratic participation. At best, the failures of positivist policy analysis are unintentional—the result of institutionalization of “hard” scientific norms and lack of attention to the social, political, and cultural aspects of decision making. At worst, false objectivity is used to compel the precarious consent of the governed—a kind of “policy public relations” intended to reproduce the *status quo* and maintain power of elites under the guise of efficiency.

Discussion of PPA has arisen as part of this more general critique, but the practice can be linked to participatory democratic techniques that originated in the new social movements of the 1960s and 1970s.^a In the most general terms, PPA is an approach to policy making and evaluation that “expands the range of actors...involved in the making and execution of public policy in a discursive or deliberative mode.”^[9] Alternatively, Igor Mayer defines PPA more concretely as:

[A] practical discipline which contributes to policy-making by designing policy-analytic fora, establishing conditions for participation, and facilitation and support of the policy-relevant debate and argumentation between the participants which take place within the forum... The analyst in PPA is an organizer of participatory fora and a facilitator of the interactions that take place within this forum.^[6]

^aThese techniques include, among others, consensus conferences, participatory action research, participatory analysis, participatory environmental planning, participatory rural appraisal, scenario workshops, and science shops.

In this model of PPA, professional policy analysts serve a quite new (and potentially uncomfortable) role as animators or facilitators of ordinary citizens' local knowledge, seeking more diverse forms of expertise to inform, and even *transform*, the political process through citizen engagement.

THE BENEFITS OF INCREASED CITIZEN PARTICIPATION IN POLICY MAKING

deLeon and Longobardi call PPA "policy analysis for the good society," claiming that the case for integrating PPA into common practice is fairly straightforward. "Citizens deserve a greater say in governance," they write, "based upon the knowledge that they are best able to articulate their special 'needs.' Given this voice as a basis for action, government can be more informed and responsive, thus promoting a more involved, engaged, and, in many perceptions, a better citizenry."^[10] Scholars and advocates of more participatory approaches argue that PPA can help governmental bodies make better decisions, resolve intractable issues, empower and engage citizens, and promote justice and equity.

Making Better Decisions

Proponents of PPA claim that greater citizen participation in policy making increases the complexity of analysis, integrates varied bodies of knowledge and experience, and enhances the relevance and timeliness of decision making. Even at the level of consultation, increased citizen participation may help policy makers make better, or at least better-informed, decisions.^[4,9] This evidentiary impact is a primary goal of PPA, particularly when a stakeholder model—one that emphasizes the importance of contributions of communities directly affected by the decision in question—is followed.^[11–13] Scholars have noted that the failures of positivist policies often result from policymaker's inability to integrate social norms, values, and the realities of living in political communities into their decision-making processes (see especially Ref.^[7]). A key benefit of PPA, therefore, is developing "a fair and impartial representation of all citizens' values and preferences"^[12] (quoted in Ref.^[14]).

Resolving Intractable Issues

Particularly in the domain of environmental issues, scholars and practitioners of PPA have argued that collaborative, participatory decision-making structures

are more likely to resolve intractable issues than decision-making structures centered on conflict and win/lose mentalities.^[15] Although they acknowledge that the quality of the deliberative process, communication between agencies, commitment to the process, and shared jurisdiction all have major impacts on the outcomes of participatory processes, Beierle and Konisky show considerable evidence that PPA does bring different parties involved in environmental planning closer to resolution, by developing common issue frames.^[16] The process of articulating common interests is important in overcoming NIMBY (not in my back yard) problems, which are often characterized by myopia and entrenched self-interest. Similarly, Broome has shown that participatory planning and design can help build consensus and develop a sense of community in protracted conflict situations, such as citizen peace-building work in Cyprus.^[17]

Empowering and Engaging Citizens

There are important benefits to PPA aside from the somewhat instrumental goals of making better decisions and resolving intractable issues, however. There is considerable evidence that participatory program design increases citizen participation and faith in governance. Recent scholars of "policy feedback" argue that as clients and recipients participate in government programs, they learn lessons about how citizens and governments relate, and these lessons have political consequences beyond the domain of the immediate agencies and decisions.^[18,19] If one of the normative goals of policy making is to create positive attitudes about government, increase citizen interest in public affairs, and facilitate participation in public life, PPA may provide an important strategy to enrich democratic practice.

Promoting Justice and Equity

At its most sweeping level of impact, PPA incorporates an argument against *containment* of people's power to make their own decisions, whether by professional experts or well-intentioned "representatives" of their interests. This argument rests on the assumption that oppression and marginalization are maintained by disparities of wealth and power and must be challenged on two fronts, by 1) directly confronting the structural maldistribution of economic and social resources, knowledge, power, and authority and 2) "animating" people to develop a collective critical consciousness in order to agitate on their own behalf. This fundamentally radical critique, drawn from traditions of popular education, assumes the capacity of everyday citizens to

generate valid analyses of their own situations and recognizes that some knowledge, values, and interests may be fundamentally incompatible (for example, the interests of the poor to a life of material and spiritual well-being as vs. the interests of elites in maintaining the status quo).

CRITIQUES OF PARTICIPATION AS THE “NEW ORTHODOXY”

Despite these potential benefits, PPA has been subject to intense scrutiny and criticism for at least a decade. Participatory methodologies have become hot topics, because these practices currently serve to fill the gap left by the withdrawal of the state under globalized neoliberal regimes. Bastian and Bastian and Cooke and Kothari, for example, argue that participatory strategies have become “the new orthodoxy” in international development practice.^[20,21] Critics argue that myopic focus on local economic regeneration or community decision making leaves scholars and activists unable to articulate a “holistic analysis of inequality and injustice...which can leave us misguidedly supporting policies which encourage participation as a further erosion of rights in favour of responsibilities, the end result of which is a continued transfer of resources from the poorest communities” (on page 175 of Ref.^[22]). Postpositivist critiques of policy making have not always resulted in convincing post-positivist methods or analytical instruments (e.g., Refs.^[6,16]), and, in this uncertain environment, concerns about PPA have taken several forms.

Lack of Attention to Social Structure

Some scholars and practitioners argue that participatory practices displace analysis of larger, structural workings of power by focusing on individual and “local” empowerment. This focus on microlevel intervention can obscure, and indeed sustain, broader macrolevel inequalities and injustice. The success of PPA for emancipatory goals relies on the transformation of major institutions, but participatory process often myopically sees the “local” as the only site available to intervention and change, while “extralocal” agencies are unmarked, universal, technical and scientific, and therefore given. The result is a grossly oversimplified view of power, which can obscure the operation of the state and other powerful interests to organize social relations in ways that reproduce social inequality. By acting as a stand-in for social justice, poorly developed or cynically practiced participatory methods easily facilitate the illegitimate and/or unjust

exercise of power (become tyrannical), acting as a screen behind which the levers of business or other powerful interests remain intact.

Implication in Devolution and Neoliberalism

It is perhaps not coincidental that attention to participatory practices has coincided with the rise of devolution and neoliberalism, particularly in the United States and United Kingdom. Ledwith argues that, since the 1970s, the twin political economic trends of devolution and neoliberalism “transform rights into responsibilities by transferring the collective responsibility of the welfare state to the individual, the family and community as moral responsibility” (on page 171 of Ref.^[22]) by hijacking the language and practices of liberatory social movements. PPA may work to reproduce this dynamic if “local” interactions take priority over the “extralocal” structures that shape them. Without attention to scale change, these techniques can serve to obliterate possibilities for dialogue, suppress opportunities for social learning, and delegitimize broad-based methods for ensuring equity, such as elections, legislative interventions, trade unionism, and solidarity politics.^[23]

Subjection Disguised as Empowerment

At worst, participatory strategies become a technology for enrolling the oppressed into their own subordination, as when participatory strategies are cynically used to overcome implementation barriers. A participatory focus can mask a wide variety of practices. Some practices simply extract a contribution of unpaid labor from the “beneficiaries” as “exchange” or in order to build “independence.” Some participatory strategies attempt to promote self-reliance, but only because project leaders assume that the participants’ dependency is the reason for their marginalization and exploitation. This can be the case with “Welfare to Work” programs in the United States that “offer impoverished women ‘choices’ that aren’t really choices, such as ‘become self-sufficient or get off welfare,’ and represent any failure as failure of the individual.”^[24] Participatory strategies can also be a simple means to manage projects efficiently or increase sustainability, a market research tool that creates the desires it purports to discover, or a public relations strategy, playing a greater role in the representation of projects to funders than in implementation. In this way, participatory strategies allow government agencies, NGOs, or other social institutions to pass hidden costs on to, while requiring contributions of labor, cash, or kind from, project participants.

PPA IN ACTION

Examples of PPA are now fairly common in the professional literature (see, e.g., Refs.^[6,11,16,17,23,25]). The few that are listed below are not intended to be a representative sample, but rather an indicator of the breadth of PPA projects.

Highlander Research and Education Center

The Highlander Folk School (later Highlander Research and Education Center), a residential self-education program, was formed in 1932 by Myles Horton, Don West and Jim Dombrowski to “train community leaders for participation in a democratic society” and to help spread democratic principles to all human relationships in every political, economic, social, and cultural activity.^[26] Their programs over the last 74 years—including workshops on labor organizing and education (1930s and 1940s), desegregation in the public schools (1950s), citizenship and voter registration (1950s and 1960s), civil rights organizing and leadership (1960s), strip mining and toxic waste dumping in Appalachia (1970s), economic globalization issues (1980s), and multilingual organizing, inter-racial coalitions and youth leadership in the American South (1990s–present)—have been incredibly ambitious. Nevertheless, Highlander’s “method” is quite simple. Highlander staffers actively recruit community organizers, bring them together in a neutral space, and facilitate them through a three-step mutual education process: 1) State and analyze your community’s problems; 2) choose a few central problems to discuss with the aid of consultants; and 3) choose a strategy and plan for action when you go back home.^[27] Highlander has sustained some outstanding community leaders (such as Rosa Parks, Esau Jenkins, Septima Clark, and Bernice Robinson) and pioneered a number of revolutionary educational techniques (for example, citizenship schools).

Consensus Conferences

The Consensus Conference is a technique, pioneered by the U.S. National Institute of Health but most popular in Denmark, which convenes a group of “non-expert” citizens to guide technological deliberations and to make policy recommendations based on consensus procedures. The Danish Board of Technologies (DBT) for example, sends 2000 invitations to a random sample of Danish citizens, and conference participants are chosen to reflect the age, gender, educational, occupational, and geographic diversity of Denmark. Participants gather for an informal set of meetings to receive background on the technology under

investigation, formulate an approach to the topic, and draft questions for a panel of experts. The conference itself begins when a variety of experts are called to make presentations, outlining their understanding and recommendations for the issue at hand. The citizen panel questions and cross-examines them and then, guided by a professional facilitator provided by the DBT, spends several days deliberating, coming to a consensus, and preparing a report outlining the issues that bear on the topic and their recommendations. Finally, they make a public presentation of their findings and the resulting report to government officials, policy makers, other citizens, and the media.

Parables to Policy

The Southern Rural Development Initiative (SRDI), a collaboration of 32 community-based institutions operating in persistently poor rural communities across 11 southern states in the United States, created the “From Parables to Policy” project in order to take advantage of the storytelling skills and traditions of rural Southerners.^b *Parables to Policy* takes community-based stories and transforms them into web-based, multimedia “parables” (stories with a purpose), intended to “serve as grist for policy dialogues that recognize and respond to rural community needs and visions.”^[25] SRDI believes that these parables serve three purposes: 1) creating opportunities for community self-discovery; 2) stimulating peer learning and discovery across the South; and 3) providing distant policy makers with alternative “hearings” to develop better understandings of southern rural poverty.

CONCLUSION

In closing, PPA may offer important resources for enriching the policy- and decision-making processes. Although policy makers, scholars, and activists should be deeply suspicious of participatory practices that displace macrosocial analysis, neglect the extralocal, eviscerate the state’s commitment to social welfare, or heighten emphasis on personal or individual responsibility under the guise of “empowerment,” broad-based grassroots citizen participation should be a feature of any genuine democracy. These techniques are particularly important to explore now, as formal political participation in the United States reaches new lows, sectarian conflict and violence grow worldwide, and economic globalization increases economic, political, and social inequalities. In this context, PPA

^b<http://www.srdi.org/parables/>

can offer new ways to foster understanding between citizens, redistribute the risks and benefits of government programs, and increase the accountability of decision makers.

Patronage and Spoils

Donald E. Klingner

*Graduate School of Public Affairs, University of Colorado at Colorado Springs,
Colorado Springs, Colorado, U.S.A.*

INTRODUCTION

Patronage is a public personnel system characterized by maintenance of political or personal loyalty through legislative or executive approval of individual hiring decisions; spoils is the practice by which successful electoral candidates reward individuals for personal or political loyalty, and secure their continued cooperation during their term of office by awarding them public jobs. Political appointees may be fired at any time; they serve at the discretion of those who appoint them.

This article discusses the following: 1) the role of patronage in democratic government; 2) patronage as a stage in the evolution of public personnel systems; 3) the relationship between patronage and political culture; and 4) maintaining patronage within acceptable limits.

THE ROLE OF PATRONAGE IN DEMOCRATIC GOVERNMENT

Patronage and spoils have long been considered essential to democratic government. But, they are also a threat to it. The relationship between patronage and civil service is intermittently marked by intense conflict, for both systems represent powerful and legitimate values. Civil service systems base decisions about whom to hire, reassign, or promote on applicants' and employees' competencies, rather than political loyalty. Just as the Constitution protects citizens from unfair actions of government officials, so merit systems protect public employees' rights to job security and due process from inappropriate partisan political pressure.

PATRONAGE AND THE EVOLUTION OF PUBLIC PERSONNEL SYSTEMS

In the United States

Public jobs were first allocated primarily among elite leaders—the small group of upper-class property owners who had led the fight for independence and

established a national government. Next, the emergence of political parties created a patronage system that rewarded party members and campaign workers with jobs once their candidate was elected. The spoils system expanded as the functions of government and the number of government employees grew after the Civil War (1861–1865). Political “machines” developed in big cities to nominate candidates and win elections. With electoral victory came the opportunity and obligation to dispense public jobs as “spoils” to those who had worked hardest for the party. The “machine” verified party loyalty, cleared applicants, and collected “voluntary” assessments from job holders to pay the party officials who had provided the job and to finance future election campaigns.

The patronage helped millions of immigrants' transitions to life in a complex urban society. Effective party machines, partisan political leaders (often serving as role models, because they were of the same culture and language as the immigrants they represented), and local precinct workers brought government to these people. In some cases, “government” was the help they needed to survive—baskets of food when they had none, buckets of coal in the winter, help in paying for weddings and funerals, help filling out immigration and voter registration forms, and sometimes a job with the city gas company or street repair department when one became available. While it does not necessarily result in the selection of highly qualified employees or provision of efficient government services, the patronage system enables elected officials to achieve political objectives by placing loyal supporters in key administrative positions. And, it exists today because elected officials get elected, and reelected, by providing information and help to citizens who feel that civil service “bureaucrats” are not able or willing to help them.

Much of the history of public personnel management can be viewed as efforts to reconcile civil service and patronage systems at an operational level. The Pendleton Act (1883) created the civil service system at the federal level, leading eventually to the development and implementation of civil service systems for a majority of professional and technical positions. The period between 1883 and 1937 is important in the development of public personnel administration

Table 1 Evolution of public personnel systems and values in the United States

Stage of evolution	Dominant value(s)	Dominant system(s)	Pressures for change
One (1789–1828)	Responsiveness	“Government by elites”	Political parties + Patronage
Two (1828–1883)	Responsiveness	Patronage	Modernization + Democratization
Three (1883–1933)	Efficiency + Individual rights	Civil service	Responsiveness + Effective government
Four (1933–1964)	Responsiveness + Efficiency + Individual rights	Patronage + Civil service	Individual rights + Social equity
Five (1964–1980)	Responsiveness + Efficiency + Individual rights + Social equity	Patronage + Civil service + Collective bargaining + Affirmative action	Dynamic equilibrium among four competing values and systems
Six (1980–now)	Responsiveness + Efficiency + Individual Accountability + Limited government + Community responsibility	Patronage + Civil service + Collective bargaining + Affirmative action + Alternative mechanisms + Flexible employment relationships	Dynamic equilibrium among competing and interacting values and systems

based on merit principles, at least partly in opposition to the disadvantages of patronage and spoils. The Civil Service Reform Act (CSRA) of 1978, passed almost a century later, was designed to maintain bureaucratic responsiveness but still protect federal career civil service from political interference (Table 1).

In Developing Countries

The modernization process appears to be relatively uniform, because pressures for modernization and democratization tend to parallel though lag behind those in the Western world;^[1,2] administrative reforms are introduced by Western consultants or exposure to the West; and Western lenders often mandate administrative reforms as a condition of continued credit.^[3]

In the first stage, the elite leaders of successful independence movements establish new nations. The transition to patronage follows as these emergent nations strive to strengthen the conditions in civil society that underlie effective government (such as education, political participation, economic growth, and social justice) by refining their constitutions, developing political parties, and creating public agencies. The third stage, if it

occurs, is a transition from patronage to merit marked by passage of a civil service law, creation of a civil service agency, and development of personnel policies and procedures. It happens due to internal pressures for efficiency (modernization) and human rights (democratization). Often, international lenders and donor governments add external pressure by tying funding to increased government capacity, transparency, and citizen participation (Table 2).

THE RELATIONSHIP BETWEEN POLITICAL CULTURE AND PATRONAGE

The transition from patronage to civil service and other public personnel systems reflects a historical process of evolution and changes in underlying values.

In the United States, the Irish bosses who ran big-city political “machines” epitomized patronage. These were based on dominant values of social conservatism and amoral familism.^[4] The exchange for votes often led to widespread electoral corruption. But the amoral familism of the community appeared to tolerate such irregularities despite exposure by the media and crusades by reformers.^[5] The demise of the Irish machines

Table 2 Evolution of public personnel systems and values in developing countries

Stage of evolution	Dominant value(s)	Dominant system(s)	Pressures for change
One	Responsiveness	“Government by elites”	Political parties + Patronage
Two	Responsiveness	Patronage	Modernization + Democratization
Three	Efficiency + Individual rights	Civil service + Patronage	Responsiveness + Effective government
Four	Responsiveness + Efficiency + Limited government	Patronage + Civil service + Collective bargaining + Privatization	Dynamic equilibrium among pro- and anti-governmental values and systems

is attributed to the challenge of new ethnics in the 1930s as well as New Deal federal programs that provided employment and benefits outside of the patronage system. By the early 1950s, most of the machines were gone or badly weakened, with Dailey's Chicago machine an anachronistic exception.^[6] By the 1960s, not only had most Irish-Americans moved away from amoral familism, but many had also become champions of mainstream values (e.g., honesty, efficiency, and impartiality) and even the modern conservative movement.

It has taken the United States over two centuries to develop an effective balance between patronage and civil service. The development of public personnel management has occurred within a context of almost two centuries of democratic government under a single Constitution, and within a civil society widely considered controlled by laws rather than individuals. Though our policy-making process is costly, complex, and tortuous, it results in outcomes that are generally considered to be transparent, effective at maintaining government authority, and politically responsive to the will of the electorate. Our tax system functions well, in spite of (or because of) its voluntary nature. While our society is deeply affected by conflicts

based on race, ethnicity, and class, it provides great opportunity for personal growth and economic advancement. Our political and administrative processes are generally open to public scrutiny by a free press and public records laws. Patronage may no longer be a major issue in most levels and sectors of government, but cynics would respond that it is less serious only because it has been replaced by corrupt contracts as a more effective means of exchanging campaign contributions for access to public officials.^[7] Thus, public personnel systems developed through successive (and successful) fights against the excesses of patronage, and against social pressures to be the "employer of last resort," in a well-developed economy that provides ample jobs outside government. Though our conflicts with corruption, cronyism, and nepotism are not completely resolved, we expect that government will provide services efficiently, using honest and qualified employees.

By contrast, less-developed countries may be characterized by factors—mostly beyond their control—that make it difficult to establish conditions of statehood we in the United States take for granted: a national identity, the rule of law, and a self-sufficient economy. Even the development of stable patronage

Table 3 How country conditions affect public personnel systems

Negative indicators	Positive indicators
<i>1. Successful Transition from Independence to a Functional Patronage System</i>	
• High reliance on charismatic leadership • Restricted freedom of speech and press • High emphasis on export of agricultural products and raw materials • Capital flight • Discrimination (race, ethnicity or class) • Inadequate electoral process	• Stable political parties • Open information and free media • Balanced, domestically-focused economic growth, including professional/technical • Domestic reinvestment of capital • Social justice (minorities and women) • Functioning electoral process
<i>2. Successful Transition from Patronage to a Functional Civil Service System</i>	
• Government process considered low on effectiveness, rationality, transparency • Widespread patronage appointments, and job retention based on salary "kickbacks" • High unemployment or under-employment • Public sector the "employer of last resort" • Underpaid, under-qualified public employees • Widespread employment discrimination based on race, gender or ethnicity • High degree of administrative formalism • High role of the military in civil society and government • Government reforms generated mainly by international economic and political pressure	• Government process considered high on effectiveness, rationality, transparency • Civil Service law, public personnel agency, and policies and procedures • Low unemployment or under-employment • Balanced economic growth/development • Adequately paid, qualified civil service • Low level of employment discrimination based on race, gender, or ethnicity • Low degree of administrative formalism • Reduced role of the military in civil society and government • Government reforms due mainly to domestic political, social and economic pressure

systems may be hampered by societal conditions (e.g., non-functional justice systems, inability to meet even minimum standards of education and health care, political leadership based on “cults of personality” rather than true pluralist political parties, and overly centralized and authoritarian political systems). These conditions generally impede the evolution of rational administrative structures and systems.^[8] For example, organizations in many less-developed countries share common structural and managerial attributes that differ from those typically found in North America, Europe, and Japan: *low* levels of role specialization, formalism, and morale; and *high* levels of centralization, paternalism, authoritarian leadership, rigid stratification, and dysfunctional conflict.^[9] Developing countries that lack a strong cultural tradition of the “public interest,” the rule of law, or a professional public service may also suffer from administrative formalism: laws, agencies, and practices that look fine “on paper” may not function well in reality.^[10] And clearly, the most significant difference is that we in this country were able to first progress from patronage to civil service, second integrate them into an effectiveness model that combined efficiency and patronage, then integrate affirmative action and collective bargaining into the mix, and finally establish the boundaries between public personnel management and emergent market-based techniques like privatization and service contracting.^[11] Developing countries today usually face these pressures simultaneously (Table 3).

LIMITING PATRONAGE AND SPOILS WITHIN APPROPRIATE BOUNDS

The relationship between patronage and civil service is intermittently marked by intense conflict, for both systems represent powerful and legitimate values. The principles of merit and political neutrality reflect the civil service ideal—a competent, committed workforce of career civil servants is essential to the professional conduct of the public’s business.^[12] Patronage diminishes organizational effectiveness and efficiency, and individual rights, in that elected officials consider political loyalty the most important selection criterion, regardless of the applicants’ qualifications. The civil service model views personnel management as a neutral administrative function; the patronage model views it as a policy- or management-oriented function under the executive branch.

Constitutional Checks

While popular political opinion focuses on the politicization of judicial opinions, in fact, a significant and

growing body of case limits political patronage in the United States.^[13]

Legal and Structural Checks

Within the U.S. national government, the Civil Service Reform Act of 1978 established that public personnel management agencies had at least two contradictory objectives—protecting employee rights and making agencies politically responsive—that required that the Civil Service Commission (CSC) be split into two agencies, the Merit Systems Protection Board (MSPB), and the Office of Personnel Management (OPM).

Conflict Among Public Personnel Systems and Values Tends to be Self-Limiting

Conflict among values and public personnel systems is limited and regulated by the dynamic realities of the competition. Because jobs and resources are finite, jobs allocated through one system cannot be allocated through others. Each value, carried to its extreme, creates distortions that limit the effectiveness of human resource management, because other values are suppressed. So, attempts by each system or value to dominate lead inevitably to stabilizing reactions and value compromises. Responsiveness carried to extremes results in the hiring of employees solely on the basis of patronage, without regard for other qualifications; or in the awarding of contracts based solely on political considerations (graft and corruption). Elected officials ensure the continued political responsiveness of civil service systems by patronage appointments of agency heads responsible for managing the bureaucracy, legislative control over agency budgets and staffing levels, and executive control over hiring decisions.

Pay for Performance and Merit Pay

Joan E. Pynes

Department of Government and International Affairs, University of South Florida,
Tampa, Florida, U.S.A.

INTRODUCTION

Public organizations need to rethink their traditional structures and reward systems to recruit, attract, and retain talented employees. Today's employees seek to be challenged and want to be provided with opportunities for skill building, a rewards system based on performance, and autonomy to complete work assignments.^[1-3] Many job seekers have an expanded view of public service; they define public service as work that provides a tangible benefit to society. Today, Americans are willing to move across the government, private, and non-profit sectors.^[4,5] Some of the common criticisms of working for the public sector are time-in-grade requirements, lower salary, and lack of variety in assignments. The public sector often does not pay competitive salaries, especially for education and experience. More traditions and expectations exist in the public sector than in the private or non-profit sectors. Public employees have come to expect lifetime employment, secure benefits, and pay raises associated with longevity. Although those expectations may have been attractive for a different generation of workers, to compete in today's labor market, public organizations need flexible options that enable them to strategically use rewards. As a way to reward talented and productive employees, various pay-for-performance/merit-pay techniques have become more prevalent in the public sector.

THE CONCEPT OF PAY-FOR-PERFORMANCE SYSTEMS

Pay-for-performance systems are grounded in the belief that individuals should be paid according to their contributions; increases are rewarded on the basis of performance rather than seniority, equality, or need.^[6] As logical as that may sound, research over the years has indicated that merit-pay systems have not achieved the expected and desired results.^[6-9]

Critics claim that the pay-for-performance evaluation process is subjective, that employees are rated by instruments that do not reflect their actual job competencies, that supervisors lack skills to develop performance standards and provide feedback, and that

comparing individuals with one another sets up a competitive environment that can be destructive to department/unit cohesion.^[10] An additional criticism is that adequate financial resources are not always allocated. For example, New York city signed a contract with the American Federation of State, County and Municipal Employees (AFSCME) District Council 37 that provides a pay raise of 8% and gives the mayor some merit-pay flexibility. However, union officials recognize that, because the contract was more generous than what city officials had originally planned for, the city would not be able to find much more in its budget for large merit payments on top of the across-the-board raises.^[11]

Even when pay rewards are not restricted, the small percentage of difference between high and low performers typically found in merit systems does not encourage improved performance or reward outstanding employees.^[6] Merit-pay systems have been condemned for focusing on compensation, rather than on improved performance. Research has found that when pay and performance are discussed, employees fail to address the developmental issues and, instead, focus on not receiving a pay increase or on receiving an increase lower than expected. When provided with constructive feedback in a training and development context, employees are likely to accept the information. However, employees process the information differently when feedback is tied to pay increases. They tend to get defensive, believing that the rater is taking something away from them by not granting a pay increase. Other research indicates that when performance appraisal results determine pay, employees often set lower goals so that they can achieve them.^[12,13]

The concepts of procedural justice and distributive justice must be considered when developing and administering pay-for-performance systems. *Procedural justice* focuses on the perceived fairness of the evaluation procedures used to determine performance ratings and/or merit increases. For example, what procedures and/or instruments are used to guarantee a link between pay and performance? *Distributive justice* focuses on the perceived fairness of the rating and/or increase received relative to the work performed.^[14] For example, are the ratings and/or increase congruent to the performance inputs? Merit systems that are not

developed with these principles in mind will lack the integrity and credibility necessary for employees to perceive that the system can discern and will reward differences in performance.

Research by Heneman indicated that for employees to perceive the process as just, five components must exist: 1) performance must be clearly defined; 2) rewards must be communicated to employees; 3) rewards must be made contingent upon desired performance; 4) opportunities such as training to improve performance must exist; and 5) the perceived relationship between rewards and performance should be viewed as important as the actual relationship.^[6] The U.S. Merit Systems Protection Board also includes the need for transparency and includes that there be checks and balances in the system (procedural and distributive justice), there be sufficient funding to provide high-performing employees with meaningful pay increases and bonuses, and the pay-for-performance systems be evaluated regularly and modified when necessary.^[15]

To be successful, pay for performance must be linked to the strategic mission of the organization and upper-level management must support the plan. Employees should participate in the development of the plan. This increases their understanding, commitment, and trust in the plan. Organizations must provide training to the raters and hold them accountable for the accuracy of their ratings.^[6,8,9,15]

The community of Aurora, Colorado, failed in its attempt to introduce a merit-pay plan. The city's supervisors were not trained in making evaluations, they were not sure what the standards were, and they did not know how to provide performance feedback. The system produced uneven results and, therefore, lacked credibility among the employees. City Manager Jim Griesemer acknowledged, "We hadn't made the investment in our supervisors that was necessary to give them the tools to do this as well as they were capable."^[16]

The less-than-favorable endorsement of merit-pay programs has not discouraged the public sector from attempting to institute them, and there have been some successes. A number of federal agencies have implemented pay-for-performance systems such as the Navy Demonstration Project at China Lake, the National Institute of Standards and Technology, the Naval Research Laboratory, the Department of Commerce, the Naval Sea Systems Command Warfare Centers, and the Civilian Acquisition Personnel Demonstration Project.^[17,18] The pay-for-performance system introduced in the Navy Demonstration Project at China Lake was funded by money reserved for step increases, quality step increases, and promotions between grades included in a pay band. An additional 0.8–1.0% was reserved for cash bonus. Employees were evaluated

on a five-level rating system, linked to the system of pay increases. Evaluation of the Navy Demonstration Project at China Lake found that money was a motivator, performance was rewarded and the rewards were considered fair, and employees believed that good and bad performances were distinguished and that the process was fair.

The City of Denver has a pay-for-performance plan. City employees' overall performances are rated as *needs improvement*: failed to meet critical performance standards; *successful*: consistently achieved performance standards; or *exceptional*: consistently surpassed performance standards. Employees evaluated as *needs improvement* are not eligible for merit increases. The amount of increase depends on the employees rating of *exceptional* or *successful* and their steps and classifications in the salary schedule (Brown, D.; personal communication, August 28).^[19]

The Town of Cary, North Carolina, developed a pay-for-performance program, in response to the Town Councils' direction to develop a program that places more of the focus on funding and rewarding the best performers. In fact, the pay-for-performance policy states the following: to support the Town's mission by encouraging employees to develop and contribute to the maximum of their potential by compensating those employees based on job performance.^[20]

The program recognizes various forms of performance through varying levels of compensation. Market adjustments to the pay plan keep the plan competitive. No automatic raises are provided, employees receive base and/or lump sum increases. The amount that employees are eligible for depends on their performance level and where they fall within the salary range. Movement beyond the market rate of pay for a pay range is reserved for employees who receive ratings of proficient or exemplary. Lump sum special performance awards of any dollar amount up to and including 10% of base salary may be awarded with the prior approval of the Town Manager. These awards may be made to individuals or groups/team members, responsible for singular achievement or accomplishments that bring special recognition to the town or generate substantial savings or create significant organizational improvements.^[20,21]

GAIN SHARING

Gain sharing is a team bonus program that measures controllable costs, such as improved safety records or decreases in waste or units of output. Teamwork is encouraged, and all team members are rewarded for controlling costs or improving productivity. Formulas are used to measure costs that are controllable, and these costs are then compared with the costs of a

historical base period. When performance improves relative to the base period, a bonus pool is funded. When performance falls short, no bonus pool is created. Employees keep a percentage of the bonus pool, and the organization keeps the rest. Charlotte, North Carolina, began a gain-sharing program in 1994. Each year, the city manager sets a citywide savings goal. If the goal is met, one-half of the savings are set aside to create an employee incentive pool and the balance is returned to the general fund.^[22-24] One-half the pool is paid, in equal shares, to all employees, and payouts from the other half depend on the achievement of department goals. Each department establishes two to five specific goals, which are selected from customer satisfaction, productivity, quality, time standards, and/or safety. If a department has three goals and meets one, employees receive 33% of the second half of their share of the pool.

Hamilton County, Ohio, has a gain-sharing program titled Project Gain. The rationale and the policy are provided below.

Hamilton County desires to reward county employees for exceeding specific performance goals above and beyond the normal scope of duties. An eligible employee participating in an approved program will be compensated based on enhanced revenues, improved efficiencies, or improved service quality that generates sustainable savings. Project Gain employee participation is voluntary. Rewards are shared by groups, not individuals, encouraging employee/employer partnership for improvement (Irwin, S.; personal communication, August 25, 2006; Stephenson, E.; personal communication, August 29, 2006).

Two projects were recently rewarded under Project Gain. Employees designed and developed a court case management application and support system that met the needs of the Probate Court. Costs associated with retaining an outside vendor to do the same were eliminated. Between \$135,000 and \$150,000 in support costs were saved. Employees received monetary awards ranging from \$800 to \$5000. The second project successfully completed was that Facilities and Public Works employees reduced the cost of snow removal at five county sites. County employees removed snow from parking lot areas, driveways, and areas previously under contract with an outside firm. This resulted in a savings of \$33,349. Employees received awards of \$1000.00 (Irwin, S.; personal communication, August 25, 2006; Stephenson, E.; personal communication, August 29, 2006).

As these examples illustrate, not all gain-sharing plans are the same. The formulas and participative management features need to fit each other and the organization. However, some common critical elements are necessary for any plan to succeed. First, there must be a credible and trusted development

process. Second, employees must believe that improved performance and decreased costs will lead to bonuses, the bonuses must be understandable and large enough to influence performance, and employees must recognize how their behavior can influence the size of the bonus. Third, employees need to be involved in the process; they must have influence over the measures used to calculate the bonus. Fourth, there must be appropriate measures, and they must focus on all the controllable costs. Measures such as units of output, materials, and supplies must all be addressed; otherwise, employees may focus on one cost, leading to its reduction but also to increases in other costs. For example, data-processing clerks may produce a greater number of records, but if the number of errors on the records has increased, the effort has been counterproductive. Or public works employees may be able to maintain and landscape more of the city's property in less time, but if the increased productivity results in equipment breakdowns and expensive repairs, then that is counterproductive. Fifth, the program must be maintained; because missions and environments change, gain-sharing formulas and programs must also change and stay relevant (Irwin, S.; personal communication, August 25, 2006; Stephenson, E.; personal communication, August 29, 2006).^[13,22-24]

SKILL-BASED PAY OR PAY FOR KNOWLEDGE

In skill-based or pay-for-knowledge pay plans, the number of tasks or jobs or the amount of knowledge an employee masters determines pay. It is a compensation system, based on paying for what employees can do and for the knowledge or skills they possess. Under skill-based pay, employees can be expected to perform a broad range of duties. Benefits attributed to skill-based pay from an organizational standpoint include developing a cross-trained and more flexible workforce, improving the flow of information throughout the organization, placing an emphasis on the work to be done rather than on the job itself, encouraging the acquisition of skills needed to perform various jobs, and increasing employees' interest in and commitment to their work. Benefits from the employees' perspective include higher motivation, increased job satisfaction, and greater opportunities for increased pay.^[25]

The Government Accounting Office (GAO), now Government Accountability Office, implemented a competency-based performance system to create a clear management linkage between employee performance and core values. Competencies are the knowledge skills and attitudes needed by any individual employee to carry out the job effectively. Individuals who contribute to the overall values and objectives of an organization are rewarded.

Twelve competencies tied to meaningful performance in GAO were identified. They are:

- Achieving results.
- Maintaining client and customer focus.
- Developing people.
- Thinking critically.
- Improving professional competence.
- Collaborating with others.
- Presenting information orally.
- Presenting information in writing.
- Facilitating and implementing change.
- Representing GAO.
- Investing resources.
- Leading others.

Employees are placed in one or five pay categories, based on their demonstrated competencies, performance, and contributions to organizational goals.^[26]

Organizations that implement skill-based pay need to be aware that wages and salaries will increase as employees learn new skills. Despite the strategic focus on skill-based training, however, many employees unfortunately will resist its implementation.^[27]

Thompson and LeHew provided a comprehensive and critical review of skill-based pay for public organizations.^[28] They developed a theoretical model that suggested broadening the framework to include a discussion of environmental contingencies, such as threat/crises, competition, and performance pressures; the proximate environment, such as the various stakeholders, unions, and elected officials; the design features of the plan, such as how radical it is, training opportunities available for employees, and the certification process that is involved; and the relevance of those components to organizational contingencies, such as workforce characteristics, managerial practices and attitudes, and congruence to skill-based pay.

CONCLUSION

There are many acknowledged problems with performance appraisals and their linkages with pay for performance/merit pay. Concerns about the accuracy of performance evaluation ratings, procedural fairness in the implementation of the reward systems, increasing competition among employees, and greater conflict between management and employees are all legitimate points.^[10,29-31] However, the risk is too great if public organizations are not willing to experiment with innovative reward programs to attract, motivate, and retain quality performers. Although the lion's share of the research on pay for performance/merit pay tends to emphasize the difficulties and problems in implementing new reward systems, it is important to note that

there have also been some successes. For new reward systems to work, the systems need to fit the organization and its values. They must be as objective as possible and designed to reward top performers, rather than to penalize satisfactory performance. To be successful, pay-for-performance/merit-pay plans need the long-term commitment from multiple stakeholders. Support must come from the elected officials responsible for appropriating funds; executives, middle managers, and supervisors; the support of the exclusive bargaining representatives in unionized environments; and financial resources to make the pay plans meaningful.^[29-31]

Pay-As-You-Go Financing

David L. Baker

School of Public Affairs, Arizona State University, Tempe, Arizona, U.S.A.

INTRODUCTION

Some governmental budgets aggregate appropriations into one unified, or consolidated, budget (e.g., the federal government). Other governmental budgets are divided into 1) an operating budget and 2) a capital outlay budget. Within the operating vs. capital outlay distinction, an operating budget represents a financial plan that proposes expenditures based on estimated revenues to finance them for a fixed period (usually a defined fiscal year). An operating budget addresses everyday activities of an entity. A capital outlay budget represents a plan for investing in capital assets (also referred to as fixed assets) that are non-recurring and endure beyond the operating budget cycle. Examples of capital assets with a long-term character include land, buildings, infrastructure, equipment, and furniture.

Pay-as-you-go financing (PAYGO) refers to public financing strategies that pay for spending increases or revenue reductions from current resources and without increasing a deficit or debt financing.^[1-3] PAYGO financing serves as a means to achieve budgetary balance and to control deficits for consolidated and operating budgets. For capital budgets, it functions in contrast to pay-as-you-use (debt) financing whereby capital outlays are paid for as they are used through debt service payments. PAYGO financing offers versatile features for consolidated, operating, and capital budgeting that require consideration within a public agency's overall budgetary and financial context.^[4,5]

The following review of PAYGO financing unfolds through several sections. First, PAYGO financing for consolidated and operating budgets is discussed. Second, the review examines the role of PAYGO financing for capital outlay budgeting in comparison with debt financing. This analysis includes capital outlay examples and an example of transitioning PAYGO financing from capital to operational costs. Third, potential PAYGO financing sources are discussed. Fourth, and finally, the review closes with a summary regarding the usefulness of PAYGO financing.

PAY-AS-YOU-GO FINANCING FOR CONSOLIDATED AND OPERATING BUDGETS

Governmental entities operating under a consolidated budget employ PAYGO financing for budgetary balance and deficit control.^[3] Federal budgeting serves as an example of this. The 1990 Federal Budget Enforcement Act (BEA) and subsequent amendments to the act establish PAYGO rules for spending and revenue legislation. Generally, congressional action is prohibited from adding to the budget deficit. Spending increases must be offset with other spending reductions or revenue increases. Conversely, revenue reductions must be offset by revenue increases or spending decreases. If full offsets are not made, funds are sequestered from certain expenditure areas.^[6]

"PAYGO is a multiyear control enforced one year at a time."^[6] Congressional budgetary actions are examined annually under the BEA on an aggregate basis, not by individual legislative bills. Federal PAYGO financing does not control spending influenced by population growth and inflation under existing law. Provisions are designed to limit growth in budgets and deficits by linking new spending to other expense reductions or revenue increases. PAYGO financing provisions shift the consequences for budgetary decisions to the stage in the process when spending increases or revenue reductions are first proposed.^[7]

PAYGO financing also refers to the operating budget strategy of assuring that public agencies deal with financial liabilities as they occur. For example, PAYGO financing is at work when pension programs routinely fund the actuarially determined contribution to cover the pension liability accrued for each payroll. This avoids accumulating an unfunded pension liability. PAYGO financing mitigates the temptation to perceive resources as available for new initiatives by allocating funds to meet known obligations as incurred. Additionally, the political desirability of proposed spending confronts the task of selling other program cuts or tax increases to offset the new costs.^[8] PAYGO financing acts as a cost-control measure.

PAY-AS-YOU-GO FINANCING FOR CAPITAL OUTLAY BUDGETS

Public agencies often rationalize PAYGO financing by the purpose of the appropriation. Deciding who will pay for a capital asset tends to be influenced by both the political and economic environments.^[9] Financing methods also introduce conflict over opportunity costs because the amount spent on a capital outlay becomes unavailable for another use.^[1] On the one hand, debt-financing advocates encourage capital assets to be purchased over time (usually the expected use cycle of an asset) by those who benefit from them. This promotes intergenerational equity in a community rather than permitting free riders to receive future capital asset benefits with no financial contribution. This also recognizes that capital assets may be needed today to support tomorrow's growth while such growth generates the revenue stream to retire the debt. On the other hand, PAYGO financing makes sense when short-term and long-term cost savings are desirable because of future fiscal uncertainty or the public agency already services substantial annual debt. Additionally, this strategy may be prudent where no significant concern exists about some citizens benefiting later while avoiding early cost participation.

PAYGO financing is the least expensive way of funding public agency capital outlays. Several relative, but material, agency cost components associated with debt financing are avoided through this financing method. The cost components identified in Table 1 are avoided in PAYGO financing. Costs identified do not include the varied, yet substantial, public agency staff and policy-maker costs associated with borrowing. These include the cost of the time involved in initiating capital asset financing, deal structuring, compiling supporting documentation, managing the project, tracking funds, and filing required financial statements throughout the life of the financing.

In addition to cost avoidances associated with debt financing, other reasons explain why public

agencies turn to PAYGO financing. First, PAYGO financing enables public agencies to manage their debt profile. A public agency's debt profile affects credit ratings.^[1] A higher credit rating translates into lower interest costs on future financings, while a lower credit rating means higher interest costs.^[10] Second, a PAYGO approach generates a certain amount of support. Because current residents often choose a specific capital outlay, there are sentiments that "the cost should not be imposed on future residents who have no say in the matter."^[11] Third, PAYGO financing encourages government to live within its means. Fourth, PAYGO financing constrains the growth of interest costs as a portion of an agency's annual budget. Fifth, and finally, the fiscal capacity of a public agency may be sufficient to fund a needed capital asset from current revenue without burdening future fiscal years.

COMPARISON WITH DEBT FINANCING

Advantages of PAYGO financing for capital outlays require evaluation against the advantages of pay-as-you-use (debt) financing. Common policy and financial considerations with debt financing include the following:

- Does a public agency have the fiscal capacity to provide the necessary resources for essential capital assets from current revenues?
- Are there timing elements that must be factored into the decision calculus of PAYGO financing vs. debt financing (e.g., state- or federal-mandated requirements, pending litigation, or an advantageous, time-limited opportunity)?
- Can debt repayment schedules accommodate the community's ability to pay with synchronized payments aligned with the enjoyment of the benefits?^[11]
- Can a public agency capitalize on low interest rates to stretch precious funds further?
- Does prudent debt financing maximize a public agency's options to invest current proceeds, to address other pressing priorities, and/or to meet unanticipated needs?
- Does borrowing avoid significant year-to-year funding variations that otherwise would be difficult for a jurisdiction to handle?
- Does excessive commitment to PAYGO financing prevent a public agency from capital outlays essential to the community?^[4]
- Does debt financing allow the cost per capita for a capital asset acquisition to decrease over time, assuming population growth? Is this a desirable feature from the community's standpoint?

Table 1 Cost avoidance in pay-as-you-go financing for capital outlays

Bond counsel
Disclosure counsel
Financial advisor
Trustee/pay agent
Official statement printing and distribution
Rating agency
Underwriter discount or premium included in the securities purchase
Insurance premiums
Credit enhancements

Public finance literature dealing with capital outlays occasionally refers to PAYGO financing as though it is an inviolate, overarching policy of particular public agencies.^[12] A public agency either follows a PAYGO financing policy or it does not follow such a policy in this frame of reference. This portrayal diverges from the more common practice of public agencies employing a mix of financial strategies to meet capital outlay needs. Each capital outlay calls for individual assessment of financial and policy issues germane to that particular capital outlay.

PAY-AS-YOU-GO FINANCING CAPITAL OUTLAY EXAMPLES

Three PAYGO financing examples illustrate the utility of this mainstream public financing strategy. Each involves a public agency investigating PAYGO financing plans for the acquisition and development of a community park. An estimated \$3.0 million is needed for the project.

Variation Examples

1. The public agency may appropriate \$3.0 million, the total cost of acquisition and development, in one fiscal year offsetting the cost with increased revenues.
2. The public agency may appropriate \$3.0 million over multiple years, assuming constant costs, in equal increments or non-equal increments that match available resources by fiscal year. Planned PAYGO financing appropriations may be advanced, suspended, or adjusted in future years based on available resources. Year-to-year funding may be assembled and preserved for a specific capital outlay purpose using an approved reserve (i.e., Good City community park reserve). Accounting treatments may vary by jurisdiction.
3. The public agency may budget and expend \$3.0 million for community park acquisition and development on a PAYGO financing basis in definable phases that coincide with each fiscal year's funding availability. For example, the first year estimated land acquisition price of \$700,000 and design development cost of \$200,000 might be budgeted and expended. In the second year, park development and landscaping, estimated at \$1.2 million, may be funded. The third year might include an estimated \$900,000 for parking, picnic grounds, and specialty areas (i.e., tot lots, volleyball courts, and nature center). At the federal level, this is referred to as "budgeting for stand-alone stages of larger projects."^[13]

Pay-as-you-go financing may be used in conjunction with other funding. Typical examples include: 1) PAYGO financing for some portion of a capital outlay while the remainder is debt-financed; 2) debt-financing a facility while cash-funding the furnishings that have a shorter useful life than the facility financed; and 3) PAYGO financing to match a grant or some other funding source dedicated to the capital outlay.

TRANSITIONING FROM CAPITAL TO OPERATIONAL COSTS

A more elaborate example demonstrates how PAYGO financing can be transitioned from a capital outlay to operating costs associated with a critically needed facility. In this instance, the capital outlay involves a \$6.0 million expansion to an existing county jail. Upon occupancy, the jail expansion affects the operating budget in a dramatic manner.^[14] Once operational, the project calls for approximately \$2.0 million in new, annual operating costs for staffing, food, utilities, clothing, and supplies. Furthermore, operational costs will escalate at an estimated rate of 12–15% annually.

Several steps are taken to finance this facility and its operational cost. First, the public agency decides to use PAYGO financing because 1) it experiences a significant, ongoing increase in property tax revenue caused by development related to population growth and 2) this financing strategy minimizes the agency's debt profile because the jurisdiction anticipates a hospital expansion project requiring \$50–75 million in debt financing within several years. Second, a \$2.0 million surge in revenues is appropriated in two places for the first year of the project: 1) a reserve designated for jail expansion construction and 2) an initial construction project allocation to cover environmental work, architect and engineering fees, and project management. Third, in project year two, the continuing dedicated revenue stream of \$2.0 million is split between building the reserve (\$1.8 million) and ongoing preconstruction costs (\$0.2 million). Fourth, in project year three, a third \$2.0 million increment is budgeted along with the previously accumulated reserve to fully fund the construction. Fifth, once construction is completed, the annual \$2.0 million dedicated revenue stream is applied to cover the ongoing operational cost of the jail expansion.

In the meantime, over the 4-year time span, the incremental growth on the base revenue stream of \$2.0 million aids in addressing the annual operating cost increase of 12–15%. This overall strategy allows a smooth transition from capital outlay to funding the ongoing operational costs as part of the total budget. Graphically, this PAYGO financing is summarized in [Table 2](#) with appropriation elements.

Table 2 Transitioning pay-as-you-go capital outlay funding to operational costs

	Project years			
	1	2	3	4
Revenue (in millions)	\$2.0	\$2.0	\$2.0	\$2.0
Appropriation (in millions)				
Capital outlay	0.6 ^a	0.2 ^a	5.2 ^b	0
Reserve	1.4	3.2 ^c	0	0
Operating costs	0	0	0	2.0 ^d

^aPreconstruction capital outlay costs (i.e., environmental work, architect and engineering fees, and project management costs).

^bComprised of \$3.2 million accumulated reserve from year two plus \$2.0 million revenue increment.

^cComprised of \$1.4 million reserve from year one, plus \$1.8 million revenue increment after covering ongoing preconstruction capital outlay costs.

^dAnticipated annual operational cost.

POTENTIAL PAY-AS-YOU-GO FINANCING SOURCES

Consolidated and operating budgets most frequently obtain PAYGO financing from three sources. First, revenue increases, both non-recurring and recurring, may provide funds for PAYGO financing. Second, spending decreases, both non-recurring and recurring, fortuitous or forced, can fuel a PAYGO strategy. Third, governmental entities may take action to rebudget funds from a lesser priority to a higher priority.^[15]

For capital budgets, PAYGO funds most frequently come from non-recurring and recurring revenue streams. However, there are other sources from which to derive such funds. Common sources after revenues include: 1) use of unanticipated fund balance; 2) non-recurring and recurring savings; 3) grants; 4) cancellation and rebudgeting of a designated reserve; and 5) rebudgeting from a lower priority to a higher priority appropriation.

CONCLUSION

PAYGO financing is an important tool in the public agency toolbox. It offers budget balancing and deficit control features for consolidated and operating budgets. PAYGO financing serves as a cost-effective, sensible alternative to debt financing. Use of this financing method for a particular policy objective requires analysis in the overall financial context of a given public agency. PAYGO financing demonstrates versatility and can be integrated with other strategies.

Finally, PAYGO financing may be utilized flexibly with a range of budgetary sources.

Pension Under-Funding: Generational Accounting Perspective

Paul J.M. Klumpes

Liyan Tang

Tanaka Business School, Imperial College London, London, U.K.

INTRODUCTION

Public pension and health-care plans and over generationally sensitive programs of many national and local governments cover the substantial majority of their population and command a substantial proportion of their governments' capital investment obligations. However, unlike privately funded health-care insurance, but similar to other types of publicly managed pension funds and social insurance, these plans are likely to encounter major long-term financial problems. This is because public health-care systems, and most other government-provided social insurance systems, rely on a "pay-as-you-go" ("PAYG") funding arrangement, whereby promised benefits and services are usually paid for by the current active workforce in the form of government taxes. However, the political will of governments to continue funding these promises via PAYG is coming under threat, because the populations of most advanced capitalist economies are ageing. This raises concern whether governments' existing and potential revenues will be sufficient to sustain current levels of public health care into the future.^[1]

Currently, there is considerable actuarial discretion over the amount, timing, and incidence of reported pension liabilities. For example, GASB Statement Nos. 43 and 45 stipulated for other postemployment benefits (OPEBs) have not resolved the issue as to ameliorating the reporting relevance and comparability of funding status of OPEB, given the long-term funding attribute of these benefits.

What is the problem with reporting pension obligations under accrual accounting systems? On the one hand, reporting funded status to a single period in the past confines the relevant information for financial statement users to the ex-post funded status at the balance sheet date that is subject to past investment performance and funding experiences. In securing the reliability of financial reporting, the funded status does not encompass the economic value of pension liabilities that capture information about long-term future cash flows. On the other hand, under the GASB, the unfunded actuarial accrued liability (UAAL) represents the excess of the actuarial accrued liability over the actuarial value of assets. A quirk of these statements is that they permit six actuarial cost methods

to be utilized in determining the portion of future normal cost allocated to the reporting period. Despite the fact that a government may use the same actuarial method for both funding and financial reporting, the comparability of funded status across various OPEB plans is considerably impaired, as the choice of the actuarial method is left to the discretion of the government. In addition, that the actuarial valuation is used for pension assets is because fair value can be volatile in the short run with fluctuations of gains and losses.

CRITICISMS OF CURRENT RULES

The short-term emphasis of current accrual-based reporting for pensions or OPEBs assume that post-employment benefits should effectively be treated as gratuities over a spot contract, where only the benefits, which "legally" accrue to the reporting period when services are rendered, should be disclosed. An underlying assumption of this perspective is the plan termination assumption, which is also known as a "wind-up" assumption. It assumes the precise amount that the firm would require to discharge its "explicit" legal obligation if the plan were terminated.^[2] Consequently, the corporate finance perspective overlooks the long-term employment expectation of pension members under an ongoing plan assumption.^[3]

Concerns have been raised regarding the perceived deficiencies in the accounting for postemployment benefits because of the long-term nature and magnitude of the defined benefit arrangement.^{[4]a} In consideration of the long-term nature of the arrangement, the intergenerational equity perspective is more consistent with the going concern principle in a lifetime contract. Generational accounting is based on the intertemporal constraint of funding postemployment benefits under a defined benefit arrangement. It generates a set of accounts for existing members as opposed to future members of the postemployment plan. Current generational accounts record the present value of cumulative contributions against cumulative benefits from

^aB13, Appendix B, Statement of Financial Accounting Standards No. 158, *Employers' Accounting for Defined Benefit Pension and Other Postretirement Plans*.

funding existing members. In constructing generational accounts, assets and liabilities of the plan are assumed to accrue to a future time when the plan is ceased for the group of existing members, as its last member exists the plan. Hence, funding status is projected to a future date. Table 1 exhibits the difference between current GASBS under the accrual accounting and the generational accounting with respect to various qualitative characteristics of financial reporting.

Note that under the generational accounting, liability is depicted as the sum of cumulative benefit obligations and unfunded benefit obligation. For OPEB, this is based on the definition of the annual required contribution of the employer for the period where the OPEB contributions should cover the normal cost and the UAAL to be amortized in the current period, under the GASBS. The present value approach is consistent with the estimate of fair value codified in GASBS31, Par. 74, considering market prices for similar investments and using discounted cash flow analysis.

In general, taxpayers, employees, and government agencies should be concerned about the buildup of assets and liabilities affecting PAYG-funded health-care systems for several reasons. First, the adoption of accrual-based GAAP highlights the extent to which the private and public sectors are exposed to unfunded pension obligations. Second, population's age, all else being equal, the growth rate of pension, and health-related liabilities will eventually outstrip the growth rate of assets. Consequently, over time, these systems can represent a major form of public borrowing against the future, which has important accounting implications.^[5] They may also powerfully affect future revenue-raising potentials of governments and the health-care premiums established by private health-care firms. Finally, as a matter of government public policy to alleviate social exclusion of the vulnerable and poor, PAYG-funded public health-care systems necessarily involve both distributional inequity, through

the provision of benefits to dependants without additional contributions, and intergenerational inequity.^[6] However such inequities are not recognized by either cash or accrual-based accounting principles used in other public-sector contexts, such as pensions and health-care provision in local communities.

OBJECTIVES OF GENERATIONAL ACCOUNTS

Appleby suggests that a major issue in the accountable financial management of any public PAYG funded system is to provide information about: 1) who pays; 2) how are these payments allocated to taxpayers; and 3) how are they used in return for a standard level of community treatment and care.^[7] However, prior researchers, evaluating the accounting control and financial management of health-care systems, have until now paid scant attention to the accountability implications of underfunded public health-care services or other services provided by local government, the department of social security, or public-sector pension funds.^[8–10]

Generational accounting is a new method of long-term financial planning and analysis. It seeks to answer the following questions: how large a government's pension funding burden does current policy imply for future generations? Is pension funding policy sustainable without major additional sacrifices on the part of current or future generations or major cutbacks in government activities? What alternative policies would suffice to produce generational balance—where future generations face the same burden as to current generations when adjusted for growth? How would different methods of achieving such balance affect the remaining lifetime funding burdens—the generational accounts—of those alive.

Generational accounts are defined as the present value of net taxes (contributions paid less benefits

Table 1 Major conceptual differences between generational and accrual-based perspectives in government financial reporting

Conceptual framework	Accrual-based perspective	Generational-based perspective
Objective	Report on interperiod equity (GASB, on page 22)	Provide information about intergenerational equity (AAS 31, on page 10)
Intended users	Present and potential taxpayers	Current and future generations of taxpayers
Recognition criteria	For each entity, revenues when earned and expenses when related good or service used	For each generation, net payments and receipts over lifetime
Applicable financial reports	Balance sheet and income statement	Statement of intergenerational equity
Assumed pension obligation	Past service costs to date, based on termination or "spin-off" calculation of accrued benefit obligation	Present valuation of future pension benefits or continuation of economic benefit obligation

received) that individuals of different age cohorts are expected, under current funding policy, to pay over their remaining lifetimes. Adding up the generational accounts of all currently living generations gives the collective contribution of those now alive toward the payment of government bills. This refers to the present value of government pension funds' current and future investments plus its net unfunded debt (i.e., its financial liabilities minus its financial and real assets, including those of public-sector enterprises). Any unfunded debt relating to past service obligations to current generations must be paid by future generations.

We now explain the relationship between accrual- and generational-based accounting perspectives in explaining the funding status of the public-sector pension fund and then briefly outlines how the generational accounts are calculated. The methodology underlying these calculations is consistent with that used in the relevant generational accounting literature.

Generational accounting explicitly recognizes generational imbalance between three inter-related variables affecting PAYG funding: 1) required contributions; 2) actual annual health-care contributions; and 3) expenditures and benefit payments. The implications of these obligations for accountability of public-sector entities to constituents is then explored in terms of the performance reporting and unfunded liability commitments, on a "fair valuation" basis. A statement of generational equity is a means to explain the incidence of these commitments across a range of taxpayers, contributors, and beneficiaries.

The concept of generational accounting, and its implications for exploring alternative basis for public sector reporting to those currently prescribed by accrual-based GAAP principles, can improve the understanding of the ramifications of incorporating the full intergenerational equity implications of continuing reliance of the underfunded long-term health-care and pension commitments.

Prior to the 1990s, the public sector in many countries did not, as a matter of practice, produce publicly available accrual-based accounts, showing a statement of their financial resources based on domestic or internationally credible GAAP. However, in 1998, the U.K. government committed itself to the implementation of accrual-based "whole of government" accounting principles as from the 2000 financial year (although most other local governments have still not yet made such a commitment). Under these proposed principles as set out by U.K. Treasury,^[11] liabilities for national insurance and other social insurance programs, or even governmental pension commitments to public-sector employees, are not recognized, because they are assumed to represent moral rather than legal obligations of government (paragraph 90 of Ref.^[11]).

Currently, the International Federation of Accountants has issued "international GAAP" for government entities that do not incorporate these implicit obligations. Instead, to date, the adoption of accrual accounting in the recording of these expenditures means that the vast proportion of these expenditures is recorded as "recurrent": capital expenditure and consumption appear to be immaterial. However, this analysis omits the future obligations likely to be imposed on future taxpayers from privately financed capital expenditure papers required to maintain public infrastructure, which Mayston suggests may be quite substantial in the public sector.^[12] Barton develops similar criticisms concerning the application of accrual-based accounting principles to the Australian public sector.^[13]

GENERATIONAL ACCOUNTING: PROS AND CONS

To the extent that real increments or reductions in a deficit indicates that future generations must help pay for the provision of generationally sensitive public-sector services to the current generation, a full accrual-accounting-based set of financial statements provides only part of the information required to assess issues of intergenerational equity. In order to assess the full intergenerational equity impact of PAYG-financed public social security programs and health-care expenditures on government financial management of countries facing demographic transition, Auerbach et al. propose a system of generational accounting that traces financial flows to and from different generations.^[14] Generational accounts indicate, in present value terms, what a typical individual stakeholder of each generation can expect to pay, now and in the future, in terms of net contributions. Thus, generational accounting indicates not only what existing generations will pay, but also what future generations must pay, given current policy and government's intertemporal budget constraint. This constraint requires that government bills not paid by current generations must ultimately be paid by future generations.^[15]

A major problem with generational accounts is that they are not broadly disseminated to the public arena, since they generally fall outside the scope of reported pension and insurance obligations, in accordance with accrual-based accounting principles. Klumpes develops a statement of intergenerational equity for underfunded health-care and public pension provisions.^[16] The analysis provides detailed intergenerational and intragenerational inequities in the funding and provision of these services, which, if present trends continue, would require increases in contributions or

taxes or decreases in service and/or benefit levels. Klumpes also develops generational accounts for specific insurance-related funds for welfare and pension provision, which demonstrates the sensitivity of public-sector accounts to the demographics of ageing populations.^[17] Tang and Klumpes exploit a fair value-based generational accounting system to investigate the effect of underfunded PAYG pensions on the financial dimensions of Chinese SOEs.^[18]

Financial statements are required to provide supplementary disclosures on the pension liability, assets, and resulting surplus or deficit on a fair value basis. U.S. companies have been reporting on this basis. The FASB proposes that the most relevant and reliable information available about pension liability or asset is based on the fair value of plan assets and a measure of the present value of the obligation using current, explicit assumptions (Summary, *Employer's Accounting for Pensions*).^[4]

The recent FASB statement as to fair value measurement, SFAS 157, clarifies and incorporates the guidance of using cash flow information and present value techniques to estimate fair value.^[4] In particular, present value techniques are identified as one of the valuation mechanisms by income approach, which converts future amounts (e.g., cash flows) to a single discounted present amount. It also implies that public-sector pension and health-care obligations should be calculated on an economic, rather than an accrual legal basis, as currently required.

Generational accounting is consistent with the present value techniques, as recognized by FASB to estimate fair value. The results, therefore, provide supplementary perceptions with regard to value relevance (herein defined as the association between financial statement measures and public stakeholders' future cash flow expectations) and disclosure implications of present value techniques in predicting unfunded pension liabilities via a generationally accountable perspective. This is in accord with the FASB's objective of including risk in the estimate of fair value, in order to replicate the market's behavior toward assets and liabilities with uncertain cash flows. Since pension assets are not always invested in risk-free assets, assumptions may be needed concerning the underlying economic conditions and monetary assets, must be identified and which have maturity dates or durations that mirror the period covered by the cash flows.

CONCLUSION

The concept of generational accounts links to the need for new reporting models in the public sector for performance reporting. The analysis is expected to raise serious questions over the reliability of (short-term)

performance measures that are now increasingly being used to evaluate the financial management of publicly financed public-sector services. This is because ageing populations imply that severe intergenerational inequities can be involved in PAYG financing of these services, which, in turn, may also underlie calculated cost and profit efficiencies that affect the long-term demand for, and supply of, these services. It is unlikely that these issues can be resolved by simply drawing up fixed short-term contracts that affect service delivery (e.g., agreements with third parties to provide recurrent services or private sector finance to fund major capital expenditures).

The calculations are based on far-reaching assumptions of life expectancy, incomes, economic growth, tax rates, and costs of providing services, inflation rates, and discount rates. Thus, these models provide a basis for judging whether the continuation of current policies should enable each generation to fund the provision of generationally sensitive public-sector services to it or whether their provision depends on future generations contributing to them as well as their own benefits.

Generational accounting is applicable to a range of other public policy settings than has been covered here, such as education- and environmental-related management. Future research is also needed to address the generational equity implications arising from the increasingly complex interactions between public- and private-sector entities in the delivery of many types of public services.

Performance Appraisal

Dennis M. Daley

*Political Science and Public Administration, North Carolina State University,
Raleigh, North Carolina, U.S.A.*

INTRODUCTION

Performance appraisal systems require a specific appraisal instrument; there are no generic appraisal processes. Each performance appraisal process is intricately involved with and dependent on the instrument it employs (as well as with the organizational and individual behaviors entailed). Focusing on the traditional question of what appraisal type or instrument to use (even if other factors are also now considered to be important) remains a central issue of concern among performance appraisal scholars and advocates.

In appraising individual performance, the search for specific performance appraisal instruments runs the gamut from the subjective (essay, graphic rating scale, and checklists) through interpersonal (rankings and forced distribution) to the objective [behaviorally anchored rating scales (BARS) and management by objectives (MBO)]. While history has, more or less, passed the subjective and interpersonal approaches by as meaningful solutions to the appraisal dilemma, reality still sees them employed quite extensively. So, an examination of these types of appraisal not only outlines the intellectual development that has led to the introduction of objective appraisal systems but, rather unfortunately, also is a look at systems—however inadequate they may be—that are still in use.

DESIGNING APPRAISAL SYSTEMS

In order to correctly employ the performance appraisal process, the answers to a series of five questions need to be explored—Why do we appraise?, What do we appraise?, When do we appraise?, Who does the appraising?, and How to appraise? These questions focus on the fundamental elements that make up the performance appraisal process.

Why Do We Appraise?

Performance appraisal is a conscientious effort at formally, rationally, and objectively organizing our assessments of others. In doing so, it is focused on the task of enhancing job relatedness. Eliminating measurement and rating errors and structuring the

decision-making process in order to accomplish this are the dual foci of appraisal research.

The purposes in which performance appraisal can be employed are numerous. However, these can be grouped into two broad categories—judgmental and developmental. While developmental and judgmental appraisals have enhanced productivity as their goal, they approach it in two quite distinctive fashions.

Development focuses on an individuals' potential rather than on their current level of skills and capabilities. Hence, it is essential in such assessments to consider the question of growth for what? Whether viewed from an organizational or individual perspective, the goal toward which this potential is directed needs examination.

Judgmental purposes follow the management systems or command and control model of authority, yet, there are serious questions as to the cognitive validity entailed in judgmental appraisals. Judgmental appraisals are also quite explicitly linked to extrinsic rewards and punishments. In fact, the existence and adequacy of the reward structure is an important subsidiary question with regard to their effectiveness. This has proved an important limitation in their use among public sector agencies.

What Do We Appraise?

Job relatedness is the chief standard by which the acceptability of a performance appraisal measurement is judged. Established through the Uniform Guidelines (1978) in response to the Supreme Court's decision in *Griggs v. Duke Power Company* (1971), the courts have repeatedly reaffirmed and explained the requirement for job relatedness in subsequent rulings (*Brito v. Zia Company*, 1973; *Ramirez v. Hofheinz*, 1980; *Zell v. United States*, 1979). Job relatedness poses a twofold requirement for organizations—criterion must enable supervisors to discriminate between employees solely in terms of their job performance, and the organization must be able to prove or demonstrate the existence of that relationship.

Job relatedness encompasses both internal, task content and external, organizational context. In addition to the traditional, essential responsibilities associated with completing a task, performance appraisals also

measure the social capital networking skills necessary for that task to be integrated into other organizational efforts.

When Do We Appraise?

In most circumstances where an annual cycle is indeed employed, the timing decision is reduced to a choice between the anniversary date and focal-point methods. Under the anniversary-date approach, appraisals coincide with the anniversary of each individual's date of employment. The anniversary-date appraisal cycle spreads the supervisor's workload over the course of the entire year. Given the large number of employees for which an individual supervisor may hold appraisal responsible, this can be advantageous. While the number of appraisals is the same under both approaches, the supervisor's ability to manage them is improved under the anniversary-date approach. With the supervisor no longer facing an avalanche of appraisals, the quality of individual appraisals should be improved.

Who Does the Appraising?

Traditionally, the immediate supervisor is most often the one responsible for appraising subordinates. Supervisory appraisal of subordinates is the predominant method and is widely suggested to occur in approximately 90% of the cases. This is the management individual deemed most knowledgeable as to the employee and the job. In fact, performance appraisal is often viewed as a key management system tool in establishing a supervisor's command and control authority. Contrastively, from a more humanistic perspective, the appraisal process is also viewed as being designed to strengthen the employee-supervisory relationship through the encouragement of mutual understanding.

Yet, there are some potentially interesting answers to this question other than that found in supervisory-based appraisal. The combination of a number of these information sources (especially supervisor, subordinate, peer, and even self-ratings) is the basis for 360° feedback. With its low hierarchy and professional staff, the modern organization is, on the one hand, forced to seek out nonsupervisory sources for appraisal and, on the other, is blessed with highly knowledgeable employees. Hence, 360° feedback promises to provide a more balanced form of appraisal. Of course, the 360° appraisal is designed to serve as a developmental instrument. When it is transformed into a judgmental appraisal, 360° appraisal loses its effectiveness (and often engenders employee distrust).

SUBJECTIVE TECHNIQUES

The use of subjective techniques is not inherently wrong. They are, after all, the foundation upon which the more objective techniques are developed. The problem with subjective appraisals centers is the basic vagueness or the idiosyncrasy, which is their essence. Subjective appraisals are the unique assessment of a specific individual. It is the resultant possibilities for inter-rater differences and errors that create the problem.

The Essay

Essays, graphic rating scales, and checklists are three of the formats that are basically subjective appraisals. The accuracy of the assessments derived when each of these formats is employed may prove exceedingly high. However, this accuracy flows more from the interactive combination of organization and individual rather than from the merits of the specific instrument being employed.

The essay appraisal format is a *tabula rosa*. Supervisors have a blank space on which they are free to write. Essay appraisals (along with the more modern audio or video log equivalents) are descendant from the traditional duty or fitness report. Almost all appraisals, including today's objective techniques, include an essay component.

The Graphic Rating Scale

The subjective graphic rating scale is perhaps still the most pervasive form of performance appraisal. Even though the trend is clearly toward the introduction of more objective systems, the graphic rating scale remains in widespread use. Rating scales remain popular, because they give the illusion of objectivity while involving little in the way of monetary costs.

Basically, a graphic rating scale consists of a set of items addressing personal traits (trustworthy, loyal, helpful, friendly, courteous, kind, obedient, etc.) and job activities (communication skills, sets realistic goals, keeps files and records up to date, adheres to policies and procedures, knowledge of job, etc.). Employee "performance" on these items is then rated using another set of adjective evaluations (poor, acceptable, fair, good, exceptional, etc.), which are invariably linked to a system of numeric scores. This enables the calculation of an average or overall, summary numeric.

Checklists and Forced Choice

Checklist or forced choice appraisals include sets of items linked to the performance of specific jobs; they

also include items for which no established relationships have been previously documented. In conducting a checklist performance, appraisal supervisors are asked to pick from a series of lists of four, those items in each set deemed to be most like and least like an employee. These are then compared against a code sheet, and only those that match validated relationships are tabulated into a Mixed Standards.

These problems can be somewhat alleviated with the use of a mixed standard scale. Mixed standard scales are checklists based on behaviorally anchored items. Specific job-related measures representing good, average, and poor levels of performance are constructed for each job responsibility or task. These items provide an added dimension and depth to the checklists. Mixed standard scales add a degree of objectivity to the format of checklist appraisals. Since supervisors are not made aware of what items “count,” distrust is fostered. Furthermore, this means that supervisors are unable to explain the basis for the employee’s appraisal.

INTERPERSONAL COMPARISON TECHNIQUES

Interpersonal comparisons, such as rankings or forced distributions, may be based on subjective or objective criteria. However, even when initially based solely on objective, job-related evidence, they experience serious shortcomings. Central to all interpersonal appraisal systems is the comparison or assessment of the individual against other individuals, rather than with the specific job to be done.

Ranking

One method for interpersonal comparisons is that of ranking. This is approached in a wholistic manner, wherein an organization’s employees are graded from best to worse. This requires complete knowledge and understanding of the entire organization—purpose and people. While perhaps feasible only in small organizations, a number of gimmicks can be used in order to extend its application to larger units.

Forced Distributions

Forced distributions are another means for making interpersonal comparisons. Grading on the curve is not a new notion and, unlike rankings, can easily be applied to large organizations. However, it is just as prone to error. Forced distributions assume that employee performance fits some external model or distribution, usually envisioned along the lines of something like a normally distributed, bell-shaped

curve. Since employees are not randomly hired, this assumption distorts the actual performance picture.

OBJECTIVE TECHNIQUES

The techniques BARS, competency-based appraisals, and MBO essentially involve the same components but approach them with a slightly different focus in mind. Hence, the objective components, which are common in all three approaches, are introduced into the appraisal process in a somewhat different order.

The BARS appraisals work best with large groups and subgroups of individuals with job descriptions that can be standardized; MBO, on the other hand, is suited such that it can be tailored to each individual job. MBO is best when it is focused on the results to be expected from job performance; BARS handles behavioral processes where outputs are more identifiable and assurable than outcomes. Both employ variations on participative management in order to guarantee their effectiveness. A somewhat more passive approach to participation guides BARS, while a more proactive style is found in MBO. Competency-based appraisal (which may follow a BARS or MBO format) substitutes the measurement of underlying skills, knowledge, and abilities for the behaviors and results that they help produce.

Behaviorally Anchored Rating Scales

The BARS are extensions of the subjective graphic rating scale. They are a clear attempt to translate the graphic rating scale into an objective appraisal system. They address and correct for many of the subjective issues that cloud the validity and inhibit the use of graphic rating scales.

Both the BARS and the MBO approaches emphasize detailed job analyses. Ideally, performance appraisal should be able to work off the same job analysis system used in the development of an organization’s position descriptions and position classification system (and be employed as a guide in the selection process and for designing training programs). Unfortunately, many organizations, especially among those in the public sector, employ different systems of job analysis when it comes to selecting people to perform a job and when it comes to assessing their performance on that job.

The critical incident technique forms the central component in the BARS system. A job analysis, complete with questionnaires and confirmatory desk audits, is conducted on similar positions. Personnel analysts and subject matter experts, i.e., incumbent job holders and supervisors, sift through the resultant

job responsibilities, activities, or behaviors to identify those that are deemed as most critical to its performance. It is assumed that these critical incidents will involve quality and quantity considerations.

MBO Appraisal

The MBO are more focused on results; however, it obviously can also be adapted to situations in which outputs or processes are more involved than outcomes. It originated as a means for managers to translate their strategic plans into implementable programs. It is a basic command and control management system for implementation and monitoring.

It is quite difficult for an MBO approach to assess performance and simultaneously identify potential. While simply having subordinate "acceptance" of performance standards is often considered to be a workable approach, MBO actually assumes that objectives are arrived at through a more actively participative process. Supervisors and employees are envisioned as discussing and negotiating performance standards that are mutually acceptable. Standards are arrived at in an atmosphere of understanding and not in one of imposition. MBO, like the BARS, approach functions better in a more participative environment.

Finally, MBO may overstate the demand for results without focusing on or directly assisting with the means for achieving them. The conditions or resources necessary for successful implementation are assumed to be provided for, automatically. Private sector organizations more readily assume that requisite resources will be forthcoming when goals and objectives are agreed upon than, unfortunately, is often the case in the public sector.

Competency-Based Appraisal

Similar to BARS, competency-based appraisal assesses an employee on the underlying "competencies" (similar to skills, knowledge, and abilities) necessary to complete the behaviors or tasks associated with specific job content. Assessing competencies replaces the measurement of behaviors and results. Since underlying competencies are used in performing many, different behaviors, validating competencies should prove to be overall easier than the more numerous individual behaviors. Since results may be due to the effort of multiple participants, the assignment of individual ratings may prove difficult, whereas the competencies necessary for achieving those results may be more easily measured. Competency-based appraisals that fail to validate the job relatedness of their competencies are simply another form of graphic rating scale.

APPRAISAL ERROR

Performance appraisal is a human process. While the tendency to focus attention on the tools used in the appraisal process can draw attention away from this, it remains the essential aspect of performance evaluation. The development of psychometric accuracy has produced performance appraisal instruments of complex sophistication. Yet, the resultant objective BARS and MBO appraisal systems are only as good as the people who use them. For all their advantages, they are still only tools for aiding us in making our decisions. Rater errors have been extensively treated in the performance appraisal literature.

Organizational Error

Much of what passes under the rubric of rater error is in reality supervisory adjustments to organizational demands. While the impact of these adjustments may be deemed as negative, they are neither accidental nor totally within the control of the supervisor to correct. Goals may be unclear or misunderstood due to communication problems. A hidden agenda may desire to use performance appraisals as means of controlling employees rather than for encouraging productivity. The expectations of what can be done can simply be unrealistic. Finally, results may be due to activity of groups rather than of individuals. The supervisors endeavor to coordinate workers and obtain productivity within this system. As such, the performance appraisal is part of the organization's overall management control system.

Rater Error

Rater errors fall into four categories: 1) job responsibility errors; 2) contrast errors; 3) unidimensional errors; and 4) interpersonal errors. In many cases, these errors are corrected through the employment of objective appraisal instruments. In other instances, more thorough supervisory training is recommended. Even though supervisors strive to objectively evaluate employees, rater errors prey on the weaknesses inherent in the cognitive process. It is this readiness with which an organization can slip into error that calls for the constant monitoring of the appraisal process.

Errors are committed whenever the responsibilities inherent in the job are substituted for a measure of the incumbent's job performance. Similarly, individuals working in a critical unit may benefit from the perceived centrality or significance of their part of the organization.

Contrast errors arise through interpersonal comparisons. Individuals are not assessed on their job performance, but on their performance compared to someone else's performance, or, as is more often the case, someone else's personal traits and characteristics.

Unidimensional errors abound. In these instances, one item dominates the evaluation process to such an extent that other critical factors are ignored. Unidimensional errors can stem from substantive or mechanical concerns.

Interpersonal biases introduce intentional distortions into the appraisal process. The extent to which a supervisor's own performance and career are dependent on a subordinate's performance, the more likely it is that favorable ratings will be awarded. This interdependence creates a mutual need for maintaining a harmonious relationship.

Training individuals in the use of these tools is just as important as the development of objective appraisal techniques. Supervisory training requires care. Supervisory training can encompass organizational and employee considerations as well as those related to the appraisal process. Performance appraisal is part of an overall performance management system. As such, its interaction with the other systemic aspects is just as important as part of its functioning as are the mechanics of the appraisal process.

CONCLUSION

Performance appraisal is the central instrument used for calibrating and monitoring employee behaviors and results. It is used to verify recruitment and selection

techniques and the appropriateness of job analyses. Performance appraisal is used in making judgments regarding pay and promotion and in exercising developmental options such as feedback and training.

While many organizations still rely upon subjective techniques or interpersonal comparisons, these fail to meet legal or objective criterion set or effective appraisal processes. Only through the employment of objective techniques, such as that found in BARS and MBO approaches will the strategic benefits of the performance appraisal process be achieved.

Even objective systems are subject to appraisal error. Organizational and structural errors arising from a misalignment or uncertainty on strategic goals and objectives can lead to distortion. Rater errors originate in cognitive behaviors that evolved for making quick decisions in simpler hunter and gatherer societies. Vigilance and continuous training are required to overcome these limitations.

Performance Audits

Brendan F. Burke

Department of Political Science, Bridgewater State College, Bridgewater, Massachusetts, U.S.A.

Wendy Haynes

Bridgewater State College, Bridgewater, Massachusetts, U.S.A.

INTRODUCTION

In general, the auditing function involves “a systematic examination of accounts or programmatic activities, so as to ascertain their accuracy; (or as) a means of verifying the detailed transactions underlying any item in a record.”^[1] Typically, a governing body engages audit professionals to obtain an independent assessment of expenses and programmatic activity to test the alignment between intended goals and actual activities. The most important dimensions—including the professionals who perform the work and their organizational relationship to the entity being reviewed—involve three primary elements: 1) the outside or third party role of auditors, serving between the principals who authorize governmental activity and the agents who carry it out; 2) the adherence to professional standards at every stage of the process; and 3) the system of its focus, wherein the auditor is bound in his or her efforts to an initial plan and a method for carrying the plan through.^[2] The ultimate goal of auditing is almost invariably found in the assessment of the effectiveness, efficiency, and economy of the use of governmental resources, the core values that underpin the executive branch of government, though additional value-based goals have been added in recent years.

This article describes the history of performance auditing and distinguishes between performance and compliance audits before exploring the performance auditing profession more specifically. The Government Accountability Office’s (GAO) standards for the performance auditing profession as well as a typical audit process are described as parts of the consistent nature of the audit profession. Subsequently, the varying components of performance auditing are described, including the collaborative work that specifies performance audit targets and a range of performance audit techniques. The study closes with a comment about the nature and disposition of the successful performance auditor.

HISTORY AND CURRENT CONTEXT OF AUDITING

Although its roots in the accounting profession can still be seen, performance auditing has moved a long

way from the stereotypical “green eyeshades,” furrowed brow, and dusty ledgers of accounting-oriented auditors in earlier times. Auditing may not be the oldest profession, but it has a long history dating back, some would say, to tick marks on Egyptian granaries in 3500 b.c. The notion of accountability forms the fundamental core of all auditing. The need grew out of the separation of a sovereign or owner from his or her riches and the consequent obligation of his or her minions to account for how those riches had been used and increased. No doubt most of the sovereign’s representatives, there to prevent embezzlement, were illiterate; hence, the annual audit was quite literally the “hearing” of accounts.^[3]

Developments around the 18th century—including the French Declaration of the Rights of Man and the American Declaration of Independence—changed the accountability relationships. Whereas the masses had been accountable to the sovereign for the use and propagation of his or her wealth, the sovereign/government was now responsible to the people. Particularly in American democracy, grounded in the separation of powers and checks and balances, the auditing profession thrives. Indeed, the current Comptroller General of the United States and signatory on the 2003 governmental audit standards, David M. Walker, refers to his staff, inspectors general, and state and city auditors as members of the “accountability” profession. Consistent with that philosophy, in July 2004 Walker announced that Congress had acted to change the name of his agency from the General Accounting Office to the Government Accountability Office and underscored the GAO’s key functions of measuring the government’s performance and holding it accountable for results.

FINANCIAL AUDITS VERSUS PERFORMANCE AUDITS

Financial auditing is ubiquitous in government, where most entities must be audited on an annual basis. The requirement may arise from an expression in state statutes or local ordinances, from the requirements of outside grantors of revenue such as the national

government or foundations, or may arise from professional values of accountability to the public. Financial audits, in their most basic form, entail a verification of financial transactions by an outside party. Financial or “compliance” audits can help in answering several lines of inquiry, including: Are records credible and reliable? Has the government been spending its resources in an efficient manner, consistent with legislative guidance, and without unwarranted additional goals included? Performance auditing is less ubiquitous, but still a broad and growing professional activity, as many governments feel the need to submit their physical operations to closer scrutiny based on the values of efficiency and effectiveness. In the government arena, both financial/compliance auditing and performance auditing fall under standards and protocols specified by the U.S. GAO in the Yellow Book, a guide updated periodically and disseminated to national and subnational governments. While there are many commonalities between the two types of audit within the Yellow Book, the two also differ in significant respects. Both share independence as a core value, but they differ in the breadth of the audit and in other technical ways (see Table 1). The accounting profession and practices underpin financial auditing, while performance auditing evolved from the internal controls systems focus of accounting, the recognition of the contribution of the social sciences to assessing program effectiveness, and the increasing importance of holding public officials accountable for government program performance.

THE YELLOW BOOK STANDARDS

The GAO creates and disseminates generally accepted government auditing standards (GAGAS).^[4] While administered by a single national government agency, there has been a movement in recent decades to insert the common framework through legislative and bureaucratic action. The GAGAS—first released in 1972—became the norm for national auditing via the

Inspector General Act of 1978, as amended, 5 U.S.C. App. (2000) and the Chief Financial Officers Act of 1990. State and local governments that receive federal assistance were required to use GAGAS with the passage of the Single Audit Act of 1984, and Office of Management and Budget Circular A-133 added the requirement for higher education institutions and nonprofit agencies that receive federal funds. In this manner, GAGAS became the uniform standard for public audits. The standards have changed significantly from the financial auditing emphasis of the early 1970s to the far more expansive 2003 revisions, reflecting a growing emphasis on performance and accountability, heightened concern with the demonstrable independence of the auditing function, and acknowledgment of the complex needs of 21st century institutions.

The standards fall into the following areas:

1. *Professional proficiency.* The organization performing the audit has certain obligations to provide for proficiency and up-to-date knowledge among its staff members. Ongoing training is as important as entrance skills.
2. *Independence.* The auditor needs to be free of personal, external, and organizational impairments to provide a fair and comprehensive audit. The auditor must not have a current or recent financial or professional relationship with the auditee, or hold any prejudicial attitudes toward the audited entity. The auditor must be free of influence by other agencies or outside forces.
3. *Professional care.* The auditor must match the method to the job, using the best practices available and not performing either more or less than the audit agreement requires.
4. *External and internal quality control.* Internal control is exercised by adherence to the Yellow Book’s professional standards, and also requires an external analysis of compliance with procedures, norms, and standards at least every 3 years.

Table 1 The contrast between financial and performance auditing

Characteristic	Finance auditing	Performance auditing
Point of intervention	Postactivity	Pre- and postactivity
Primary targets	Individuals/accounts	Individuals/programs
Primary mechanism	Rules	Incentives
Role of sanctions	Negative	Positive
Role of management	Supervision/discipline	Goal setting/reinforcement
Role of oversight	Detection/enforcement	Evaluation/benchmarking
Complexity of strategy	Simple	More complex
Durability of effects	Short term	Intermediate

The standards apply to both financial/compliance and performance audits, but there is more flexibility to the procedures and techniques in the performance auditing realm. This is discussed here.

THE PLACE OF JUDGMENT IN THE AUDIT PROCESS: RISK ASSESSMENT AND TECHNIQUE

Fig. 1 illustrates a fairly typical performance audit process. The process proceeds through the following steps: risk assessment/annual planning, preaudit or preliminary survey, planning, field work, reporting, and follow-up. As mentioned previously, two important differences between financial and performance auditing are the breadth of potential and actual coverage of performance auditing activity, and the range of possible techniques for performance auditing, which involves more choice and discretion.

The risk assessment/annual audit planning process (first column) is discussed next. An individual performance audit will typically begin with a preliminary survey of the organizational landscape. In the “survey” phase, the audit team seeks to educate itself quickly as to what is occurring in the program, identify problem areas, and obtain reliable and relevant information for use in planning and performing detailed review work. Information obtained may include program mission, purpose, and objectives, governing laws and regulations, key management reports, reviews conducted by others, and data sources/key metrics for performance measurement. Frequently, the team will interview top officials and staff within and outside the program and may also test a sample of transactions in various management and service delivery systems.

Careful planning is vital to a successful performance audit. During this phase, the audit team leader/manager narrows and defines the scope of the audit and determines audit objectives. She or he writes a work

plan, develops timelines, and determines the mix of resources—expertise, experience, equipment, supervision—that will be needed and assigned to complete the work in accordance with GAGAS. Toward the end of this phase, the audit manager will typically meet leaders of the program to be audited and apprise them of the scope and duration of the review.

During the field work phase, the audit team gathers and analyzes data acquired through various techniques, including file and document review, testing transactions, observing staff in action, interviewing key players, assessing program outputs and outcomes, and much more, depending upon the scope and nature of the audit work plan. Even with adequate planning, the auditors often encounter unanticipated problems and opportunities in the course of the fieldwork. The natural temptation is to continually expand the scope of the audit, and it is especially important during this period that the audit managers exercise good judgment in deciding which new issues should be added to the scope of the audit and which should be cycled back into the annual audit planning process.

Toward the end of the field work and into the reporting phase, the audit team develops findings and recommendations, briefs the auditee on the findings, and reports the results to management and leadership of the audited entity, as well as other interested parties. Other interested parties may include a legislative body, an oversight agency, or the public more generally.

The follow-up phase, too often neglected by performance auditors as a result of limited resources, entails the monitoring of management’s corrective actions in response to the findings and recommendations. Ideally, the results of the follow-up work then become another element to be considered in the annual planning process.

As has been noted previously, the process outlined in Fig. 2 ideally occurs in a broader planning context. The scope of possibilities of auditing governmental performance is as large as the budget or the work force

Fig. 1 Performance audit/review process.

Fig. 2 Process for developing annual performance audit plan.

of the given unit; hence, an important focus of the performance audit function is the determination of what to audit. This relies on a triage function of sorts, based on various risk factors, or questions to be asked after the range of auditable entities have been identified: 1) How large are the dollar amounts of potential audits? Larger is probably a better subject for performance audit. 2) Who oversees the function and acts as the primary funding source? Those who appropriate their own tax revenues are probably the highest priority. 3) Has the program or function had recent problems or major changes? These events probably signal the need for more immediate audit attention. 4) Does the program involve a high degree of public contact? These may also merit more immediate audit work. 5) Has management expressed concerns about the program? Management concerns should be accorded weight in setting the audit agenda. Given limited resources, the auditors must exercise strategic judgment about the focus and scope of their planned audit work, while still preserving enough flexibility to respond to emerging issues.

In keeping with the standards for independence, the audit leadership should retain final discretion in determining the scope and focus of annual audit work, but should also engage management in the process and keep leaders fully apprised of the status and outcome of audit work.

Compared with professionals drawn from other disciplines, one sees relatively fewer traditional auditors (i.e., accountants) engaged in conducting performance audits. Professional guidance on planning and conducting performance audits may be obtained through

certification programs, training sessions, and written guidance from such organizations as the Institute of Internal Auditors and the National Association of Local Government Auditors.^[5] Performance auditing draws on a broad spectrum of professional expertise, including engineering, law, economic analysis, and the full range of social scientific inquiry. This analytical diversity is reflected in the range of possible techniques available to the performance audit team, including:

1. *Process analysis*—The study of the sequence of activities necessary to accomplish governmental work. The allocation of time to portions of the process, proper ordering and potential parallel coordination of activities, geographic or locational alignment between scheduled activities, and assignment of varied expertise and effort throughout the process may determine the overall efficiency and effectiveness of the complex service. Process analysis is a central component of total quality management improvement efforts.
2. *Quasiexperimentation*—Assessment of a program change or intervention over time, in comparison to a control group wherein the status quo without the program change is maintained. If the control and intervention groups are comparable at the outset, the quasiexperiment will display differences in outcomes that can only be driven by the specific different policy treatment between the two groups.
3. *Surveys and focus groups*—Written evaluation or open discussion regarding programmatic characteristics, gained from either direct participants

in service delivery, or clients who receive the service, or both. The use of these participant information gathering techniques will depend on whether the auditor needs answers to narrower questions, whether she is exploring factors related to service delivery, whether the participants require anonymity or not, and other characteristics of the situation.^[6,7]

While the performance audit field is open to a diversity of analytical methods, it is moving toward a common reliance on data related to programmatic performance. Four variable groups increasingly tend to be the analytic focus: Inputs—dollars and human resources for use with government programming; Process—steps within the delivery of governmental services, such as customer contacts, Web pages created, or documents produced; Outputs—the product of governmental effort, such as building inspections, public health nurse visits, or training sessions held; and Outcomes—the desired impacts of government (e.g., crime reduced, birthweight of babies increased, lives saved through safety programs, and the like.^[8,9]) Each type of measure can be the focus of a performance audit, but should ultimately be connected to positive programmatic outcomes. Another core measurement tool and audit procedure involves benchmarking. If a certain service has an accepted standard, or if a government can be compared to a favorable measure in a reputable jurisdiction, the government is working against a benchmark. Many services have been tied to benchmarks, but there is still a long way to go to arrive at accepted standards of measurement for the range of government services.^[10,11]

CONCLUSIONS

This description of the performance audit has listed the components common across compliance and performance variations, as well as the common framework dictated by the GAO's GAGAS or Yellow Book standards. But in addition, the differences within performance audits have been described, including topics to be analyzed and techniques used in the analysis. Ultimately, the performance auditing professional is as much an artist as she or he is a scientist, working from a broad mandate with an abundant toolbox of techniques and broad discretion in approach and focus. The performance auditor is best able to pursue her or his job when she or he "thinks like an auditor," exercising curiosity, independence, broad awareness, clarity, and is convincing in her or his presentation.^[12] With the

current emphasis nationwide on issues of performance and accountability, performance auditing will continue to be a growth industry.

Performance Indicators in State Administration, The Use of

Peter J. Haas

Department of Political Science, San Jose State University,
San Jose, California, U.S.A.

INTRODUCTION

Performance measures are numeric indicators of activity integrated into government budgets and other planning documents to help ensure accountability and establish the link between resources and results, in theory. Many state governments have implemented performance measurement systems.^[1,2] The critical aspect of performance measurement is the selection, definition, and application of appropriate measures of government activities, such that the quantity, efficiency, and effectiveness of service delivery efforts may be accurately documented.

Creation of a performance management system entails much more than merely identifying performance measures. Moreover, under ideal circumstances, performance measurement efforts are integrated into a framework for improving government decisions as part of a *performance management system*. For example, the state of Virginia defines its performance management system as follows:

- **Strategic planning:** Systematic clarification and documentation of what an organization wishes to achieve and how to achieve it.
- **Performance measurement:** Systematic collection and reporting of information that track resources used, work produced, and intended results achieved.
- **Program evaluation:** Systematic collection and analysis of information to determine a program's performance and reasons for achieving the level of performance.
- **Performance budgeting:** Systematic incorporation of performance information (planning, performance measurement, and evaluation information) into the budgetary process (Fig. 1).

Thus, performance measurement is ideally not an end itself, but is linked to other management tools. The following steps are typically involved in the creation of a state strategic planning effort that includes performance measurement:^[2]

1. Identification of the populations served and outcomes sought by the agency
2. Identification of specific outcome indicators by which progress will be measured
3. Examination of the future environment and problems/barriers within which the agency and its programs operate (such as demographic, economic, and social factors and trends)
4. Identification of the latest available baseline values for each outcome indicator
5. Examination of alternatives and practical options for achieving outcomes, including the current service delivery approach
6. Analysis of each strategic option's costs, feasibility, and effect on the outcomes, including estimates of the out-year values for each outcome indicator and the costs included in the plan
7. A process for obtaining input from the legislature, agency customers, agency employees, and interest groups
8. Selection of one or two of the strategic options for review by key state officials in the executive and legislative branches

BENEFITS OF PERFORMANCE MEASUREMENT

Performance measures may have other uses beyond informing resource allocations decisions. Among the other benefits associated with performance measurement are improved managerial accountability, improved relations between administrators and elected officials, and improved relations with citizens.^[3] Liner et al. list the following possible reasons for governments to engage in performance measurement:^[2]

1. To respond to elected officials and the public's demands for accountability.
2. To help formulate and justify budget requests and policy choices.
3. To help in resource allocation decisions.
4. To raise questions as to why outcomes are not meeting expectations and to trigger in-depth examinations of why performance problems (or successes) exist.
5. To help motivate personnel to continuing program improvements.

Fig. 1 Relationship between elements of a strategic planning system. *Source:* From <http://www.dpb.state.va.us/VAResult/HomePage/PMOverview.html>.

6. To formulate and monitor the performance of contractors and grantees (performance contracting).
7. To provide data for ad hoc, in-depth program evaluations.
8. To support strategic and other long-term planning efforts (by providing baseline information and subsequent tracking of progress toward long-term goals).
9. To help identify “best practices.”
10. To communicate better with the public and to build public trust.
11. Above all, to help provide better and more efficient services to the public.

CHARACTERISTICS OF PERFORMANCE MEASUREMENT SYSTEMS

Although most share many of the broad characteristics described earlier, state performance measurements systems vary considerably in practice. For example, how broad should the focus of the measurement effort be? Some states have developed statewide goals, benchmarks, or similar reports for the state as a whole, without a particular focus on the more specific roles of state government and state agencies. This approach—typified by Oregon’s Benchmarks, Minnesota’s Milestones, and Florida’s Governmental Accountability to the People Commission—may be more accurately categorized as state quality-of-life indicator systems rather than state-government-focused plans. Even among states that engage in a more applied version of performance measurement, the scope of the effort may differ considerably, ranging from plans that focus on a few agencies providing extensive, well-prepared strategies, outcomes, and performance measures, to less intensive reports from agencies that merely described current activities without much discussion of the future environment, outcomes, or out-year targets.^[2]

A second key characteristic of state performance measurement systems is the extent to which, if any, they are integrated into performance budgeting. A review of state performance measure systems found

that relatively few states actually incorporate performance measures into their budget process.^[2] Without a meaningful linkage to state budget process, performance measurement may become an empty gesture. One factor that apparently limits the extent to which states integrate performance measures in budgeting decisions is the lack of expertise and other resources required to do so. One observer noted that “using data on results to guide government management practices has proved to be successful in states and localities across the nation. Few jurisdictions have, as of yet, succeeded at using results data to shape budgets.”^[4]

A third characteristic is the locus of performance measurement analysis. In some states, agencies bear the primary responsibility for analyzing data, an arrangement that some find to be problematic: “Agency and program managers have had difficulty in systematically analyzing and using outcome data as part of the budget formulation process. Agency personnel often appear to consider outcome information something they are required to provide, rather than as something useful to them in preparing and justifying their budgets.”^[2] States with a strong legislative analysis arm may be more likely to make good use of performance measurement data.

CHALLENGES ASSOCIATED WITH IMPLEMENTING PERFORMANCE MEASUREMENT

A survey of local government managers identified issues that frequently arise with respect to the use of performance measure.^[3] Among the most commonly reported problems were the following:

1. maintaining the currency of measures
2. measuring the quality of programs and services
3. avoiding ambiguity and confusion with measures
4. compilation and distribution of measurement data in a timely manner
5. lack of capability to analyze collected performance data
6. maintaining support from lower-level employees for performance measurement efforts

The last problem is particularly critical, because an ongoing performance measurement system requires considerable effort from all levels of an organization. “Performance measurement systems are more effective in influencing behavior in desired ways when line managers and employees buy into the system and measures.”^[3]

UNINTENDED CONSEQUENCES

Performance measurement is not without difficulties, costs, and potential risks and pitfalls. Among those that have been identified are the following:^[5]

1. Selection of performance indicators with inadequate attention to who will use the data and how. Without a practical focus, indicators will not or cannot be used by anyone.
2. Inadequate preparation among legislators and executive branch managers for application of results-based government. Decision makers must understand how to use performance measurement data.
3. Inadequate linkages between information on funding and agency activities to the desired outcomes. Measuring performance may be relatively simple compared to establishing meaningful links between indicators and budget processes.

Beyond the sheer cost of collecting and analyzing performance data, perhaps the greatest potential risk associated with performance measurement systems is the potential for creating incentives for agencies that are based on instrumental indicators rather than genuine measures of performance. Instrumental indicators are indirect or inaccurate measures that are used in the absence of bona fide performance measures. Typically, instrumental indicators are linked to agency

inputs or efforts rather than outcomes or results of those inputs. For example, the performance of a drug treatment program might be measured in terms of the number of clients who receive treatment, rather than on the outcome of the treatment. If agencies act to maximize their performance as measured by instrumental indicators, they may not actually improve their actual performance in terms of desired outcomes.

Does performance measurement live up to its promise? It is now apparent that it is frequently used to measure the impact of government programs and services. Its potential, therefore, is now widely accepted. The extent to which performance measurement really improves state government is still largely unknown.

Performance Measurement

Patria de Lancer Julnes

Department of Political Science, Utah State University, Logan, Utah, U.S.A.

INTRODUCTION

Performance measurement refers to the production of information about an organization's performance (e.g., inputs, outputs, outcomes, efficiency) with regard to services or programs. Performance indicators should be derived from the organization's mission, goals, and objectives.

A key feature of performance measurement that differentiates it from other similar efforts is that it is ongoing. Measurement occurs regularly (e.g., weekly or monthly), and the resulting information is available on a real-time basis for monitoring results by management, elected officials, and citizens. The information can also serve as the basis for modifying plans to enhance performance, whether through the (re)allocation of resources or the development of goals and objectives. Also, it can help to provide justification for budgets and investment decisions, and keep organizations accountable and responsive when reported out. Thus, results of performance measurement are useful to organizations' internal and external stakeholders.^[1,2]

HISTORICAL DEVELOPMENT

The practice and concept of performance measurement are not new to the public sector. Measurement of program activities can be traced back to Taylor's scientific management approach in the early 1900s. Scientific management was so well regarded in the private sector that this approach to measuring inputs and outputs was quickly embraced in the public sector. By the 1930s, performance standards and work measurement had been introduced in several government agencies. Several professional organizations also developed grading systems to assess administrative performance. One of these organizations was the International City-County Management Association (ICMA). In 1938, under the authorship of Simon and Ridley, the organization published *Measuring Municipal Activity*. This publication suggested several types of information that local governments could use to monitor local services and to assess how well these services were being delivered. Included in the publication were measures of needs, costs, results, and efforts.

Other non-profit organizations have also been supporting performance measurement efforts in the public sector. One of the most notable is the Urban Institute, whose contribution began shortly after its founding in 1968, with the development of methods for government and human services to measure the performance of their programs.

Performance measurement has been an important component of numerous management reform efforts to improve performance. Early efforts, between the 1940s and 1970s, such as planning programming budgeting system, management by objective, and zero base budgeting, had measurement at their core. In the 1980s and early 1990s, total quality management, emphasized data collection and process analysis. Today, the measurement of performance on a regular basis is the cornerstone of the Managing for Results effort, a comprehensive approach to focusing an organization on its mission, goals, and objectives. Managing for Results links measures to program mission, sets performance targets, and reports regularly on the achievement of target levels of performance.^[3,4] Further, performance measurement is also the common denominator of the Chief Financial Officers Act, passed in 1990, and the Government Performance Results Act (GPRA), passed in 1993.

TYPES OF PERFORMANCE MEASURES

To understand how performance measurement information is used, it is helpful to distinguish several types of performance measures differing in terms of what is being measured. A good performance measurement system is said to be one that combines the various types of measures or indicators.

Fig. 1 helps to illustrate these different types in the context of an inoculation program conducted at a public health clinic and follows the program logic model. The indicators shown are not exhaustive in that many more could be added, but they provide a simple way to illustrate the various types of performance measures.

Input Measures

As illustrated in Fig. 1, input measures are often devoted to the accounting of resources. These may

Fig. 1 Example of indicators: an inoculation program.

include dollar costs, staff and staff time, materials, and other resources. Input indicators tell us the amount of effort in delivering services and are used for accountability purposes. The example here includes the amount of funding, number of personnel who will provide the inoculations at the clinic, ancillary personnel, and equipment necessary for service delivery.

Workload or Activity Indicators

Workload or activity indicators deal with issues such as things that need to get done to provide the service (processes), incoming work, and work that has not been completed. They are not useful for public accountability per se, but they can help management track the workflow of their programs.^[5] In some settings, it is difficult to distinguish these measures from output measures. An indicator of workload might be the number of vaccination records filled.

Output Measures

Outputs are the final product or service delivered that ultimately, it is hoped, will lead to a desired outcome. Outputs are indicators of administrative or process effects. In our example, an output is the number of children who received the vaccines. Other outputs for a public health clinic include handing out brochures on the advantages of early inoculation and following up after tuberculosis testing.

Outcome Measures

Earlier attempts to measure performance were often limited to measures of inputs and outputs. However, the growing recognition that producing outputs does not always produce desirable results led to the emphasis on measuring outcomes. Outcomes are the consequences of outputs and are more complex. In our example, the inoculation program would only be

considered effective if it resulted in lower infection rates. Consider a flu vaccination program based on a different strain of the virus than the one that later reached epidemic proportions. In this case, the output did not result in an effective program. Yet, outcomes also include negative consequences. For example, if people become sick as a result of the flu vaccine, this is also an outcome.

In Fig. 1, the box labeled “better society” is included to remind us of the ultimate goal of public programs and policies. Although policy analysts rarely need to concern themselves with defining a better society, it is useful to reconsider even end outcomes from time to time. For example, the reduction of public medical expenses that result from the elimination of childhood illnesses might seem an obvious desired end outcome. However, some research suggests that a complete lack of exposure to illness may have negative consequences for the long-term development of a child’s immune system. Thus, outcomes are not an end in themselves, but a vehicle to reaching even greater values that lead to improvements in society as a whole. For that reason, it is useful to distinguish intermediate outcomes and end outcomes.^[5] Then, following with our example, a lower incidence of the targeted illness is an intermediate outcome; improvements in the quality of life of clients and reduced medical expenses are end outcomes that follow from the lower incidence of illnesses. The final goal is a better society.

Efficiency Measures

Also called productivity measures, efficiency measures indicate the ratio of output to input or outcome to input. When there is an increase in efficiency, it means that there are more gains for a given amount of effort. As is inherent in its definition, efficiency requires knowledge of the amount and type of inputs, the types and number of outputs, or the types and number of outcomes. Thus, in our example, an

efficiency measure can be calculated by dividing the number of children inoculated by the amount of funding (output-to-input ratio), or by dividing the reduction in incidence of infection by the funding (outcome-to-input ratio).

Explanatory Information

The Governmental Accounting Standards Board (GASB) suggested that government entities also include explanatory information when reporting performance. This information, qualitative or quantitative in nature, can help to illustrate the successes of the programs or services or provide information on why the program has not achieved expected results. Thus, it can help to interpret or put the obtained indicators in context. Together with input, output, outcome, and efficiency measures, explanatory information forms part of what the GASB calls service efforts and accomplishment indicators. Going back to the example in Fig. 1, an explanation for success could be that the program used a flexible schedule of services strategy to ensure that the program reached those children in households where parents or guardians worked during traditional business hours. Developing these explanations requires that the appropriate information is recorded and, within practical limits, the more indicators that one is measuring, the better the quality of the interpretations that one can make.

Complications of Measurement

Research shows that input and output indicators are more often developed and used than outcomes and efficiency indicators.^[6,7] Input and outputs are the more traditional types of performance indicators, but as noted above they do not say anything about the desired effect. A greater emphasis is now placed on the need to measure and report outcomes. However, measurement of outcomes is complex in that it is often difficult to distinguish the true consequences of a program from those caused by non-program factors. For example, in the health clinic example, it is difficult to determine how many people would have gotten a particular disease if there had been no vaccination program.

Conversely, it is also difficult to verify that illnesses appearing after the vaccination were caused by the vaccine. One of the major complaints of government employees involved in performance measurement is the difficulty in measuring outcomes because, they argue, it is often not possible to follow up with clients long enough to know whether the service or program had the desired effect. Thus, unlike the straightforward relationship of inputs to outputs, the relationship of inputs to outcomes is less clear and thus superficial

analysis runs the risk of overlooking the possibility that the observed relationship is in fact spurious. This has led to a debate as to whether this kind of causal analysis is appropriate from ongoing performance measurement or should be conducted in a full-blown program evaluation. This is elaborated in the next section.

Furthermore, obtaining a single measure of overall efficiency, even with ideal indicators of outcomes, can also prove to be difficult. This is particularly the case when dealing with multiple inputs and outputs or outcomes with different units of measurement. A suggested approach to overcome these difficulties is to use a technique such as data envelopment analysis, a linear programming technique.^[8] However, this solution is only appropriate if the organization has the technical capacity to analyze performance data.

CURRENT INITIATIVES IN SUPPORT OF PERFORMANCE MEASUREMENT

Many initiatives have contributed to the current emphasis on performance measurement. Two that warrant additional attention are GPRA and the American Society for Public Administration's (ASPA) Center for Accountability and Performance (CAP).

The Advent of GPRA

As noted above, since the early 1990s, performance measurement attained greater visibility at the federal level with the passage in 1993 of the GPRA. This act, the touchstone of then Vice President Gore's National Performance Review initiative, was designed to improve the effectiveness of federal programs and citizen satisfaction through the systematic measurement and reporting of performance.

Under GPRA, federal agencies are required to develop quantitative performance measures and targets, and to report these indicators to help monitor their performance.^[9,10] These federal requirements are having collateral effects, in that performance measures are increasingly being expected at all levels of government. Current research reports an increasing number of public organizations indicating that they have some type of performance measurement system.^[7,11]

CAP

In 1996, an ASPA task force recommended that CAP be created as a standing committee, or as a center to address the extensive emphasis and requirement for all levels of government to move to performance-based,

results-driven management. To that end, CAP's mission is to improve the practice of public service by helping ASPA members to acquire the knowledge, technical skills, and resources necessary to successfully Manage for Results.

In support of its mission, CAP provides numerous training and information resources. These include a performance measurement workbook, *Performance Measurement: Concepts and Techniques*, and case studies prepared by local, state, and federal government practitioners, describing their application of performance measurement and management, strategic planning, and Managing for Results.

Other important resources are the monthly CAP corner in ASPA's *PA Times*; a three-part video series, *Managing for Results: The Key to More Responsive Government*, which provides insights from national leaders on implementing results-oriented government; a multimedia CD-ROM training program, *Applying Performance Measurement*, cosponsored with the ICMA, the Urban Institute, and Public Technology, Inc.; a monthly Brown Bag Lunch on Performance Measurement and Evaluation, which is cosponsored with the U.S. General Accounting Office and George Washington University; and a web site (<http://aspanet.org/cap/index.html>) with extensive web links to performance measurement-related web sites and major best practices web sites.

CONTEMPORARY ISSUES

Utilization of Performance Measurement Information

Much research on performance measurement shows that in spite of its long lineage, development of systematic performance measurement systems is not as prevalent as one might expect. Furthermore, even organizations that have developed performance measures do not implement them in the sense of using the information in decision making.

With this lack of utilization, a key concern has been understanding the factors that affect it. Some identified lack of training, unavailability of data, resources, and other rational and technical issues, whereas others argued that political factors such as lack of support from elected officials and management inhibit utilization. Yet, others focused on the lack of an organizational culture that supports measurement and use. This existing controversy over such factors can be reconciled if we recognize that there are different stages of utilization.^[6,12]

First, there is the issue of adoption or development of performance measures. Organizations in this stage

of utilization have developed, what is called in the knowledge utilization literature, a capacity to act.^[13] This means that even though the knowledge has been produced, it can remain dormant. Research suggests that whether public agencies develop a performance measurement system is a function primarily of rational/technocratic factors, such as those mentioned earlier.

Second is the implementation stage or converting the knowledge into action, actually using the information. A complication at this stage is that, as the organization moves from adoption to implementation, more political risks and culture barriers emerge. Further, complicating assessment of implementation is that use can occur in various ways. Many who promoted performance measures envisioned instrumental use, in which the information guided a decision. However, as evidenced in evaluation theory,^[14] the actual use of performance measurement information can range from very subtle or for enlightenment to very concrete or instrumental.^[12] An example of enlightenment would be when performance measures are used for monitoring purposes, thus allowing for reflection about the program in question. An instrumental implementation would be the case for immediate resource allocation decisions, something that according to recent research does not happen often.

Distinguishing these two stages has useful implications for improving utilization of performance measures. It appears, however, that long-term success of performance measurement has an additional requirement—that the use of performance measures be sustained long enough to allow for an accommodation between the performance measurement system and the organization. This implies a need for a long-term commitment to continue to develop, implement, and refine performance measures.

Citizens' Participation

A greater emphasis is being placed today on involving citizens in performance measurement and performance improvement efforts. One of the arguments for this involvement is that it can help to (re)build public trust in government and lead to long-term sustainability of performance measurement.^[15,16] Furthermore, citizens' involvement in performance measurement can lead to a more impartial, objective, and useful measurement system, and can create greater accountability among policy makers.^[17] Involving citizens, however, requires overcoming practical concerns. These include the need to invest time and money, ensuring diversity so that the clients the programs serve are properly represented, and ensuring democratic participation.

Performance Measurement and Program Evaluation

It was noted earlier that performance measurement may be limited in its ability to develop outcomes. Related to that is the current debate questioning the value of performance measurement vis-à-vis program evaluation in promoting productivity improvement efforts.

One can begin to consider this question by highlighting the differences between performance measurement and program evaluation. The main difference between them is that the latter answers the “why” questions, and the former answers the “what” questions. Also, program evaluation tends to be a one-time (or a not-too-often) activity, whereas performance measurement is ongoing. Thus, they both have different purposes.

Performance measurement is best able to help with general oversight on a day-to-day basis, and program evaluation is particularly suited to providing a more indepth view on how to improve operations.^[3,18] When properly done, performance measurement can provide data for program evaluation, and program evaluation can provide information to help refine performance measurement. Accordingly, performance measurement and program evaluation can complement and strengthen each other and need not compete.

Performance Measurement and Benchmarking in Local Government

David N. Ammons

*Institute of Government, University of North Carolina at Chapel Hill,
Chapel Hill, North Carolina, U.S.A.*

INTRODUCTION

For more than half a century, local governments have been encouraged to measure their performance.^[1] Today, leading professional associations in local government promote the practice.^[2,3] But what is performance measurement? What are the principal types or categories of measures? How does performance measurement contribute to local government administration? What distinguishes performance measurement from the related endeavor called *benchmarking*?

PERFORMANCE MEASUREMENT

Performance measurement is the art of gauging systematically the quantity, quality, efficiency, and effectiveness of goods and services produced by a department, program, or activity. Ideally, a set of performance measures not only will reveal *how much* work has been performed or *how many* units of service have been delivered, but will also report *how efficiently* the services were produced, their *quality*, and their *impact* on service recipients or on the community in general.

Performance measurement is extolled by its proponents—first, for its value as a method for ensuring the accountability of a local government and, second, for its usefulness as a tool supporting a host of managerial functions. How can a local government consider itself to be meeting its accountability obligations, these proponents ask, if the government's reporting focuses solely on financial stewardship and the avoidance of improprieties with public funds, but fails to provide meaningful evidence that commensurate services were secured with these resources?^[4] Although it is a crucial element of accountability, financial stewardship addresses only one part of the accountability question. Information about what the citizens receive in return for their tax dollars addresses the other part.

WHY MEASURE PERFORMANCE?

A sound performance measurement and reporting system enhances the accountability of a local government.

Frontline employees and their supervisors become more accountable for performing a fair day's work; departments and programs become more accountable for achieving their objectives; and the local government as a whole becomes more accountable for delivering a good return to the tax-paying public. Some local governments stop there, emphasizing the importance of performance measurement for accountability but using their system for little other than reporting on programs and services. Others go further—much further. They, too, use performance measures for various reporting purposes, but they also rely on their performance measurement and monitoring system to support a host of other management functions.^[5–8] These other functions include planning and budgeting, program evaluation, performance appraisal, reallocation of resources, directing operations, contract monitoring, the identification of deficiencies and opportunities for operational improvement, and the testing of strategies and processes designed to effect performance improvement.^[9] Categorizing the multiple purposes of performance measurement in a different fashion, performance measures may be used to evaluate, control, budget, motivate, promote, celebrate, learn, and improve.^[10]

As noted by Hatry, “Unless you are keeping score, it is difficult to know whether you are winning or losing. This applies to ball games, card games, and no less to government productivity.”^[11] When fully developed and applied, performance measurement fulfills this vital scorekeeping role for local governments, not only alerting local officials to deteriorating conditions or service delivery problems, but also informing them of general operating strengths and weaknesses and the degree to which various procedural modifications or program strategies are achieving their intended results.

TYPES OF PERFORMANCE MEASURES

Although attempts at categorizing performance measures occasionally have produced lists of 8 or 10 different types, many of these categories may easily be

combined to form a simpler set of four basic categories of performance measures in local government:

- Workload (output) measures.
- Efficiency measures.
- Outcome (effectiveness) measures.
- Productivity measures.^[9]

The first of these categories, workload measures (also called output measures), is well represented in city and county budgets and other performance-reporting documents. Examples of workload measures include “applications received,” “properties appraised,” “meters read,” and “tons of refuse collected.” Unfortunately, many of the local governments that report raw workload measures begin and end their performance measurement effort with this category. This is unfortunate because workload measures have the least managerial value of the four types of measures. Raw workload counts tracked over time reveal patterns of demand for a given service and reveal the scale (and perhaps even the “busy-ness”) of an operation, but they yield few managerially significant insights.

Efficiency measures relate the outputs of a program or activity to the amount of resources required to produce these outputs. Unit costs (e.g., cost per application processed) are efficiency measures, as are the many variations that link outputs and resources in other ways (e.g., applications processed per \$1000). Some variations replace dollars with another form of resource input, such as labor-hours or staff-hours, yielding measures such as applications processed per staff-hour.

Outcome (effectiveness) measures reveal the extent to which a program is achieving its objectives. Measures of service quality are often included in this category. Rates of success in limiting fire spread and recovering stolen property in the fire and police services, respectively, are examples of effectiveness measures.

Productivity measures gauge the efficiency and effectiveness of an activity by means of a single indicator, sometimes in the form of an index. Such measures may relate total costs to program successes (i.e., total costs divided by successful interventions rather than by all intervention attempts, regardless of whether successful or not) or may report production ratios that have been reduced to account for any defective work (a common practice in mechanic productivity calculations). Productivity measures have also been called “outcome-based efficiency ratios.”^[5]

Program officials and supervisors attempting to “steer” their operations—to borrow a term from the movement to “reinvent government”—can benefit from a good set of performance measures.^[8] A good set of fleet maintenance measures, for example, can help officials improve performance in the local government garage not only by keeping them apprised of the

condition of the fleet, the quality and efficiency of repair work, and the availability of vehicles, but also by tracking improved results or conditions that confirm the value of maintenance practices that are working well and by alerting operating supervisors and managers if performance begins to fall short of the intended mark.

It is important to remember that the various measurement categories are not of equal managerial value. Workload measures rest at the bottom of this scale. Managers who discover, for example, that the rate of on-schedule refuse collection service (effectiveness) has declined or that the cost for this service per household (efficiency) has soared will be prompted by this discovery to investigate further and to devise strategies to return the service to its previous condition or to an even more favorable performance level. In other words, these measures of efficiency and effectiveness will inspire managerial thinking.^[12] No such managerial thoughts are likely to be inspired by raw workload measures. Reporting the number of tons collected or households served is unlikely to prompt the manager to examine any aspect of the operation or disturb the status quo.

CRITERIA FOR A GOOD SET OF PERFORMANCE MEASURES

A good set of performance measures includes measures that are valid and reliable, understandable, timely, resistant to undesired behavior, comprehensive, non-redundant, sensitive to data collection costs, and focused on important facets of performance.^[5,7,13,14]

- *Valid*: High scores on a set of measures should be a reflection of true excellence on important qualities or dimensions of service.
- *Reliable*: Measures that are consistently accurate and exhibit little variation attributable to subjectivity or measurement by different raters are said to be reliable.
- *Understandable*: The meaning of each measure should be unmistakably clear.
- *Timely*: Measures that are fresh have greater value to operating managers and policy makers.
- *Resistant to undesired behavior*: An emphasis on performance results could tempt employees to take extreme or otherwise undesired steps to attain good marks. It is important to have well-designed measures that are unlikely to prompt such steps or that address performance from several dimensions simultaneously, thereby discouraging actions that would lead to good marks on only one dimension while undermining others.
- *Comprehensive*: A good set of measures addresses all the major facets of an organization’s performance.

- *Non-redundant*: Each measure should add a distinct, unduplicated element of performance information to the set.
- *Sensitive to data collection costs*: Most dimensions of service may be measured in several ways—some direct and some indirect or involving proxies. When measurement of a given function presents serious challenges, various options should be considered carefully, weighing the cost required to collect the measure against the potential value of such information.
- *Focused on important facets of performance*: A good set of measures will address the most important dimensions of a program or department's performance.

Not all sets of performance measures achieve these criteria. The best ones do or at least come close.

BENCHMARKING

Among public sector managers, the term *benchmarking* may be used to refer to any of three related management practices. Each practice features the use of a known or fixed point of reference to gauge current conditions or the status of performance, to inspire improvement, and to track progress toward a desired condition or performance level. In the most ambitious applications, benchmarking also entails the analysis of selected operating processes, to identify variations that account for superior performance among those deemed the “best in the business” for purposes of adapting “best practices.”

Benchmarking is a term borrowed from the vocabulary of land surveyors. Once surveyors pinpoint a spot of known location and elevation, they have a point of reference—that is, a benchmark—for other measurements. Similarly, managers can use performance benchmarks as points of reference to guide their efforts to improve program performance. Potential choices as performance benchmarks include relevant performance standards, statewide or national norms, and the performance targets or results achieved by respected counterparts.

Benchmarking takes three forms in the public sector:

- Corporate-style benchmarking.
- Use of benchmarks in “visioning” initiatives.
- Use of performance statistics as benchmarks.

Each form differs from the others. The common denominator is the use of points of reference called benchmarks in all three.

Corporate-Style Benchmarking

Derived from the practices of Xerox, Motorola, Digital Equipment Corporation, and other pioneers of benchmarking in the private sector, this form of benchmarking is more analytical than the others and narrower in that it focuses on a single process within an operation. This is the classic search for “best practices,” in which a government adopting this form of benchmarking would identify organizations regarded as outstanding performers of the selected process, analyze the process in place at these top performers to detect the reasons for their outstanding results, and adapt these “best practices” for use by the benchmarking government to improve its own performance. This form of benchmarking has been defined as follows:

Put quite simply, benchmarking is the art of finding out—in a completely straightforward and open way—how others go about organizing and implementing the same things you do or that you plan to do. The idea is not simply to compare your efficiency with others but rather to find out what exact process, procedures, or technological applications produced better results. And when you find something better, to use or copy it—or even improve upon it still further.^[15]

The essence of corporate-style benchmarking has been identified most simply as four steps: plan; collect; analyze; and improve.^[16] A slightly more detailed formulation designed in the late 1990s for implementation in the public sector identifies corporate-style benchmarking as a seven-step process: 1) decide what to benchmark; 2) study the processes in your own organization; 3) identify benchmarking partners; 4) gather information; 5) analyze; 6) implement for effect; and 7) monitor results, taking further action as needed.^[17,18]

Use of Benchmarks in Visioning Initiatives

From time to time, some communities undertake planning initiatives to establish a vision for their future. When they do so, they typically articulate desired conditions and sometimes quantify these conditions in the form of benchmarks. Organizers of such efforts usually enlist broad community support, including local government, and measure their success in terms of progress toward the benchmarks.

This form of benchmarking has garnered more media attention than the other public sector forms, although most of the attention has been directed toward state-level visioning initiatives such as the Oregon Benchmarks.^[19,20] Community undertakings of a similar nature, such as the “Life in Jacksonville (Florida)” project, typically focus on local socioeconomic

conditions and quality of life rather than the mechanics of local government service delivery.

Use of Performance Statistics as Benchmarks

Local government officials who compare their own organization's performance statistics with national standards, norms, or the performance statistics of other organizations providing similar services are practicing yet another form of benchmarking. Benchmarks here are the standards, norms, or performance levels shown to be achievable by other programs or service producers.

This is probably the most common form of benchmarking in the public sector, even if it is less publicized than the version associated with visioning initiatives. Although comparison of performance statistics involves less depth of analysis than corporate-style benchmarking and is less likely to lead directly to the identification of "best practices," this form nevertheless enjoys the benefit of greater breadth as a diagnostic tool. Comparisons are rarely limited to a single process or a single component of a given department, as are corporate-style benchmarking projects, and can often reveal operating strengths and weaknesses more broadly, sometimes as a prelude to more detailed analysis.

CONCLUSION

Performance measurement is an important tool not only for fulfilling a local government's obligations for accountability, but also for guiding its efforts to achieve successful programs and services that are efficient and effective. Benchmarking is an advanced application of performance measurement that takes three forms in local government, each designed in its own way to lead to service improvements or to enhanced community conditions.

Performance Measurement: Citizen-Driven

Kathe Callahan

*School of Public Affairs and Administration, Rutgers University,
Newark, New Jersey, U.S.A.*

INTRODUCTION

Performance measurement in the public sector is the systematic and continuous assessment of how well services and, in some instances, products are being delivered. A good performance measurement system can increase the knowledge about public sector service delivery and, therefore, enhance the decision-making process of elected officials and public managers. It can also strengthen accountability systems in that the public has an increased understanding of what they are getting, or not getting, for their tax dollar. Performance measurement results in information that can be used to inform decision making and inspire managerial thinking. Performance indicators typically measure the quantity, quality, efficiency, productivity, and outcomes of public services.^[1]

Citizen-driven performance measurement involves the use of measures, or indicators, that are socially relevant to citizens. By socially relevant, we mean measures that are understandable to the average citizen and inform them about the quality of life in their community and the quality of service delivered by a government agency. Socially relevant performance measures provide citizens with comprehensible data that enable them to hold government officials accountable for performance and enable them to answer the question, “Am I getting value for my tax dollar?” So, in addition to collecting data on the tonnage of refuse collected in a quarter, a public works department might also collect data on street cleanliness. The cleanliness rating of a street means more to the average citizen than the overall amount of garbage collected. Citizens, elected officials, the media, and other interested stakeholders can use relevant data, such as street cleanliness ratings, to hold public administrators accountable for their performance. Data such as this can also be used as a benchmark to improve service over time and foster competition among service providers. Socially relevant performance measures equip citizens with the information necessary to ensure accountability and to ensure that governments and public agencies do what they are supposed to do, ultimately improving the quality of people’s lives.

Ideally, citizen-driven performance measurement entails citizens being involved in the establishment of

appropriate performance indicators. If citizens are not directly involved, public administrators, at the very least, should consider the value that the performance measurement system, or specific performance indicators, has for citizens and should willingly share performance data with the public in a timely and understandable way.

ACCOUNTABILITY AND PERFORMANCE

Until recently, government accountability was largely a matter of financial accounting, hence its name. When public funds were appropriated, the key accountability questions focused on how much money was spent and on what items—personnel, supplies, travel, or communications. Today, the concept of governmental accountability has taken on a much broader meaning. According to Romzek, Dubnick, and Shafritz, accountability is a relationship in which an individual or agency is held to answer for performance that involves some delegation of authority to act.^[2] Accountability mechanisms are the means established for determining whether the delegated tasks have been performed in a satisfactory manner.

Thus, governments, in an effort to demonstrate accountability, must be able to measure what they do. Specifically, they need to show their constituents:

1. What they are getting for their tax dollars, in terms of services—a police presence, public hospitals, roads, airports, libraries, public education, and water supplies.
2. How efficiently and effectively their tax dollars are spent—cost per mile of roads built to certain standards and cost per pupil of students graduating from high school.
3. How such expenditures benefit their lives or the lives of those they care about—eradication or suppression of diseases such as polio and acquired immune deficiency syndrome (AIDS), high sense of security in a neighborhood, and safe and reliable water supplies.

This type of accountability holds government responsible not only for its accounts but also for the

results of its actions—the impact of each service on each citizen.

To emphasize to constituents what they are getting for their tax dollars, governments need to be able to measure and report what they are accomplishing. Measures that are unreported, suppressed, or poorly reported are virtually useless in improving performance. Well-reported (i.e., easy to understand and widely distributed) performance measures emphasize how well a government is doing at meeting its constituents' needs and at living up to its commitment to provide quality services for the taxes people pay. Performance measures can help elected officials, public managers, and citizens understand the impact various expenditures have on the quality of their lives and the lives of those they care about. Performance measures also enable elected officials, public managers, and citizens to see the outcomes, or results, of specific government services and to place a relative dollar value on each service provided. Measures of progress have the added benefit of breaking through negative stereotypes to build lasting support for public services.

Measurement of performance has always been implicit in questions of outputs and outcomes: Is crime up? Are the streets cleaner? Is the air quality better? How well are our children doing in school? In short, is the program producing as promised? What are the results? Performance measures provide an opportunity to answer such questions with hard data, rather than the more common situation-subjective statements based on vague assessments of efficacy: “the neighborhood seems safer,” “litter here is worse than ever,” or “the schools in this town are pretty good.”

It is helpful to think of performance measurement as a process, or system, of measures and procedures, whereby organizations assess how well they are doing compared with previous performance, compared with other organizations (benchmarking), compared with national standards, and in terms of how well they are achieving their stated goals and objectives. A well-designed performance measurement system should clearly articulate service goals and objectives, define service outputs and outcomes, and specify the expected quality levels for these outputs and outcomes.

To measure something—IQ, weight, speed, attitude, blood pressure, rushing yards per game, and on base percentage—you need to quantify what it is you want to measure by using a defined set of rules. Obviously, some things are more difficult to measure because they cannot be observed directly or there is no agreed-upon standard on which to base the measurement. We know that to run the mile in under 4 min is an exceptional performance, and we know that a blood pressure reading of 160/100 is something to be concerned about. We know this because these measures have an accepted standard on which to compare other

measures. Public sector services are often more difficult to measure because, for mission-driven organizations, there is, more often than not, no agreed-upon standard of performance and no bottom line. Not driven by profits, or stock value, public managers operate in a world of multiple, often-competing, and often-vague expectations of what good performance looks like. Yes, it is more difficult to measure the performance of the Department of Homeland Security than it is to measure the performance of Coca-Cola or Nike, but it can and should be done.

Performance measures can be quantitative (average response time) and qualitative (how safe people feel in their neighborhood). Managers can develop performance measurement systems incorporating various performance indicators, such as those defined by the Government Accounting Standards Board (GASB).^[3]

- *Input indicators:* These measure the resources expended on a program, such as the amount of money spent or the total number of employee hours needed to deliver a service.
- *Output indicators:* These report the quantity of products or units of service provided to a service population. They also include “workload” measures that reflect the amount of effort expended to produce a product or provide a service. Examples of output indicators include number of meals delivered, miles of road paved, or number of students passing the high school proficiency test.
- *Outcome indicators:* These measures report the results of programs and services. Outcome indicators possess quantitative and qualitative aspects. Examples of outcome indicators include the number of individuals employed 6 mo after participation in a job training program or percentage of residents who feel safe in their neighborhood.
- *Efficiency and cost-effectiveness indicators:* These measures focus on how a goal is achieved, rather than what was achieved. Specifically, efficiency indicators refer to the ratio of the level of service (tons of refuse is collected, number of meals delivered, and number of flu shots administered) to the cost, in dollars and labor, of providing the services. They measure the cost per unit of an output or outcome. Examples of efficiency indicators include cost per meal delivered, cost per ton of garbage collected, and cost per flu shot administered.
- *Productivity indicators:* These measures, according to Ammons, combine the dimensions of efficiency and effectiveness in a single indicator.^[4] For example, the number of meals delivered per hour measures the efficiency, and the number of meals delivered on time (and warm) measures the effectiveness. The unit cost (labor-hour) per on-time delivery measures productivity. To determine the

productivity indicator, the cost of late deliveries, as well as the on-time deliveries, is included in the numerator of such a calculation, but only on-time deliveries are included in the denominator, thereby measuring efficiency and effectiveness.

Designing a good performance measurement system may be challenging to managers not accustomed to measuring or setting performance targets. However, this effort should not be dismissed as too complex or too difficult. Developing a system involves an understanding of what the program is trying to accomplish, who the main users or customers are, and a basic knowledge of the current level of services. A good performance measurement system should include the following seven-step system developed by the National Center for Public Productivity, a research center affiliated with the School of Public Affairs and Administration at Rutgers University Campus at Newark:

1. *Identify the program to be measured:* To start with, programs to be measured must be clearly defined. Programs are groupings of routine activities aimed at providing support for specific public services. Groupings of individual activities make up a program. For example, the following activities—street resurfacing, street patching, seal coating, and curb repair—constitute a program that is traditionally called street maintenance. Usually, programs are defined by governments and are generally listed on an organizational chart contained in the operating budget. Programs relate directly to the organizational structure and the managerial areas of responsibility. Choosing which programs to measure is a matter of judgment. On the one hand, programs should not be too few, so that only a small portion of services are covered or the information collected is insufficient. On the other hand, too much reporting can be excessively costly or overwhelming and impractical. Generally, performance measurement systems work best when they concentrate on collecting limited, but essential, information about basic programs that need the most managerial oversight and where accountability reporting is most important.
2. *State the purpose and identify the desired outcome:* Typically, a government department or agency initiates a strategic planning process to clarify its mission, goals, and objectives. Through this process, the agency can identify the outcomes, or results, it wants to achieve through its programs. A manager can only measure the performance of a program if its purpose is clearly stated. Preparing a well-articulated statement of purpose is an important first step. Ideally, a clear mission statement is the starting point. If that is not available, a thorough program description is a good place to begin. For example, GASB offers the following statement of purpose for a public transportation system: The basic purpose is to provide safe, dependable, convenient, and comfortable transportation services at minimum cost to the citizens, including special clients groups such as the handicapped and the elderly.^[5]
3. *Select measures or indicators:* A good system uses a few selected indicators to measure outcomes and performance. Most government programs that have established performance measurement systems incorporate the indicators described earlier in this chapter: input, output, outcome, efficiency, and productivity. For example, in a maternal health clinic, the input measures might be the number of labor-hours, the operating budget, the number of clinics, or the cost of supplies. Output measures could include total population served, number of pregnant women served, or number of prenatal visits provided. Outcome measures might include number of full-term deliveries, number of premature births, or number of low-birth-weight babies. Efficiency measures could include labor-hours per woman served, dollars spent per 1000 infants, or dollars saved as a result of healthy babies, and productivity indicators could include measures such as the cost per full-term delivery or the cost per 100 deliveries.
4. *Set standards for performance and outcomes (performance targets):* Under this step, public managers should specify the conditions under which program goals and objectives are met. Managers need to determine what service effectiveness and quality means for a particular program and explicitly state how they are going to determine whether the stated terms of effectiveness and quality have been met. This involves comparing actual program outcomes or results with some agreed-upon standards, including previous performance (the percentage of residents who feel safe in their neighborhoods this year compared with last year), performance of similar organizations (the percentage of residents who feel safe in their neighborhood compared with the percentage in a neighboring community), performance of the best organizations (the percentage of residents who feel safe in their neighborhoods compared with the percentage of residents who feel safe in their neighborhoods in the recognized “safest communities” in the country), and preset targets

(next year, 85% of all residents will feel safe in their neighborhoods, and in 3 yr, 95% will feel safe). Performance targets should be realistic. They should reflect an attainable standard. Unrealistic performance targets, both unattainably high and insultingly low, demoralize staff members and contribute to dysfunctional behavior.

5. *Monitor results:* Each performance target should be monitored on a continuous basis. Monitoring provides the manager with the results needed to decide whether the performance targets have been met. Systematic and periodic monitoring gives the manager an opportunity to keep tabs on the operation of the program and take corrective action when necessary. Usually, monitoring will vary, depending on the program and target accomplishments. For the most important programs and services, monthly data collection and reporting systems that indicate results will be necessary.
6. *Performance reporting:* A good performance measurement system reports program results on a regular basis. The report focuses on what was accomplished and what it costed the public. Reports should be brief, should convey information graphically, and should include minimal explanatory information. Information should be presented in such a way as to facilitate comparisons over time, comparisons with similar organizations, and comparison with best programs nationwide and against preset targets.
7. *Use outcome performance information (analysis and action):* Information from an effective performance measurement system is regularly used in program planning to re-evaluate goals and objectives, and to adjust priorities. Another use is in managing for results where outcome information is used to promote continuous improvement in program operations and results. A well-developed performance measurement system will enable managers to spot weaknesses and challenges to program delivery, as well as program strengths and opportunities for improvement.
8. *Performance management:* It is useful to distinguish between performance measurement and performance management. Performance management is broader than performance measurement. Performance management incorporates the results of performance measurement into general management practices. The National Performance Review defines performance management as the use of performance measurement information to help set agreed-upon performance goals, allocate and

prioritize resources, inform managers to either confirm or change current policy or program directions to meet those goals, and report on the success of meeting those goals.

It is essential that performance measurement be considered an inherent and indispensable part of the management process. Measurement for measurement's sake alone is insufficient. Managers can have stacks of data at their fingertips, but unless they use that data to improve policy and procedures it is virtually useless.

GETTING CITIZENS INVOLVED

Citizen involvement in performance measurement can help public managers stay focused on what really matters in their communities. Citizen involvement can increase the impact of performance measurement by encouraging managers to look beyond traditional output measures (that often have little meaning to citizens) and, instead, focus on quality-of-life issues and community goals. When you think about it, why do managers care about government performance? They want to improve the quality of service delivery and, ultimately, the quality of life in the communities they manage.

The overall goal of involving citizens in performance measurement is to build lasting processes that involve citizens in assessing municipal performance, so that government policies and services reflect the needs of the community. Citizens and public managers, together, can establish performance measures that are meaningful to both citizens and managers. So, for example, instead of just calculating the tons of refuse collected, public managers might also ask citizens to rate the cleanliness of their streets. Instead of counting the number of squad cars deployed to specific neighborhoods, public managers could ask citizens how safe they feel in their own neighborhoods or in city parks.

The relevance of performance measures increase when managers incorporate citizens' perceptions. A powerful management tool results when public managers combine or compare traditional output measures with outcome measures that reflect citizens' perceptions. For example, city managers might learn that an increased police presence in a residential area has no correlation to a citizen's feeling of safety in that neighborhood. Yet, increased police presence in public areas, such as city parks, directly affects a citizen's feeling of safety. Meaningful measures that the average citizen can understand provide citizens with the opportunity to assess government performance and influence how government services can be made more responsive to community needs and priorities.

Although citizen participation can ultimately improve the level and quality of municipal service provision by making services more responsive to the needs of citizens, it is often difficult to achieve. Citizen involvement typically results in effective policy and meaningful public sector programs;^[6–8] yet, active citizenship is often perceived as burdensome, costly, and time consuming.^[9,10] Performance measurement systems may be easier to design and implement when citizens are excluded and when managers are the ones determining what will be measured and how it will be measured. Although easier to design and implement, such performance measurement systems fall short in terms of measuring what matters most in a community. Citizen involvement increases the social relevance of indicators by combining facts—hard data—with value—how citizens feel. With citizens involved in making decisions, acceptance of the decision may increase, enhancing the likelihood of successful implementation and reducing the amount of vocal opposition. As involvement increases, citizen understanding of governmental operations may increase and criticisms of governmental agencies may lessen, improving the plight of the often-criticized public administrator.

Although challenging, strides are being made. In the United States, in recent years, we have seen the opportunities for citizen involvement in performance measurement increase. The National Neighborhood Indicators Project, an initiative of the Urban Institute in Washington, DC, has been successful in what they refer to as democratizing data to meaningfully involve citizens in the measurement of government performance and to use neighborhood-level data in local policymaking and community building.^[11] The Boston Indicators Project, a partner in the National Indicators Project and one that is recognized as one of the best local level initiatives in the country, relies on broad measures of performance that communicate value. They ensure that public services are responsive to the needs of the citizens, not the convenience of the service providers. They involve the public in making data meaningful to the broadest segment of the population, stimulate public discourse around government performance, and track progress on shared goals and objectives to hold government accountable. The goal of the project is to engage citizens, community-based organizations, the media, the business community, and government in meaningful dialogue to develop a better understanding of the opportunities and challenges confronting the city. They stimulate informed public discourse by effectively communicating data with a broad segment of the population and together, with the community, they track the progress on shared goals and milestones.^[12]

There are various approaches to including citizens in performance measurement efforts, and it is up

to public administrators to select the appropriate approach for their community based on the unique characteristics of that community. Meaningfully involving citizens is not a one-size-fits-all approach. Public administrators need to find the right approach for their jurisdiction, and they need to build trust with citizens. A half-hearted approach will only add to the level of frustration and cynicism that many citizens have toward government. In finding the right approach, it may help to revisit the seven-step performance measurement system discussed earlier in this entry, but this time incorporate citizen involvement in each step. Reflect on your community and think about the most appropriate ways to involve citizens in each step. It may be appropriate to establish a citizen advisory committee, or an ad hoc committee of citizens, to achieve some of the objectives. In other instances, a citizen survey might be required. The revised seven-step process might look something like this:

1. *Identify the programs to be measured:* To start with, programs to be measured must be clearly defined by citizens and public administrators. Choosing what programs to measure is a matter of judgment, and citizens should have an equal voice in determining what programs are to be measured. Programs that are identified by citizens should be recognized as a community priority.
2. *State the purpose and identify the desired outcomes:* A government department or agency, in collaboration with the citizens it serves, should initiate a strategic planning process to clarify its mission, goals, and objectives. Through this process, the agency and citizens identify the outcomes, or results, they want to achieve through agency programs.
3. *Select measures or indicators:* Citizens and managers should determine the most appropriate measures for each program, rather than relying exclusively on the data collected by individual programs. The most responsive program measurement systems use citizen surveys, or some other appropriate mechanism, to assess citizen satisfaction and perceptions.
4. *Set standard performance and outcomes (targets for accomplishment):* Under this step, citizens and public managers should specify the conditions under which program goals and objectives are met. Citizens and managers need to determine what service effectiveness and quality means for a particular program and explicitly state how they are going to determine whether the stated terms of effectiveness and quality have been met.

5. *Monitor results*: Each accomplishments target should be monitored on a continuous basis by the management and staff delivering the service and the citizens receiving it. Monitoring provides the citizens and managers with the results needed to decide whether the performance targets have been met.
6. *Performance reporting*: Reports are shared with citizens, elected officials, the media, and other government watchdogs. Performance data should be presented in a way that is meaningful to citizens, so that they can understand what is happening in their neighborhood, as well as in the community as a whole.
7. *Use outcome and performance information (analyses and action)*: A well-developed performance measurement system will enable citizens and managers to spot weakness and challenges to program delivery, as well as program strengths and opportunities for improvement.

CONCLUSION

Improving the outcomes and results of public sector programs, and the performance of government in general, can be realized when performance measurement systems are more closely aligned with accountability mechanisms and when citizens are meaningfully involved in both the concepts. Appropriate, relevant, and objective measures of performance can be developed when citizens are meaningfully involved in defining performance targets and in framing and shaping performance indicators. The appropriate, relevant, and objective measures that result from this process can then be used to hold individuals and organizations accountable for results that actually matter. Citizens can assume a more significant position in their relationship with government, when they are meaningfully involved in dialogue and deliberation surrounding the establishment of goals and objectives for public sector programs and public sector service delivery, when they are asked what good government looks like to them so that they can help establish appropriate performance targets, and when they are recognized as an integral part of legitimate accountability systems. Accountability systems are more effective when they are based on trust and recognize the primacy and importance of accountability to the public.

Accountability for performance is strengthened when multiple stakeholders agree on what good performance looks like. When citizens and service providers collectively agree on the standards and outcomes that reflect effective governance, relevant accountability mechanisms can be established. And when performance information is widely shared with the public, citizens are able to hold government accountable for results.

INTRODUCTION

Performance reporting is the conveyance of information, about activities and accomplishments and their related costs, by persons who are responsible for achieving something for those to whom they are responsible. Performance reporting is a form of feedback that is essential in all organizations—for-profits, nonprofits, and governments. Performance reporting is indispensable in the fulfillment of the stewardship and accountability obligations of organizational leaders to those outside the organizations who have entrusted their money and other resources to the leaders. Reporting performance in governments and nonprofit organizations, though, is uniquely different from reporting performance in for-profit businesses.

DIFFERENCES BETWEEN FINANCIAL AND PERFORMANCE REPORTING

In businesses, the most critical element of performance is to be profitable. Profit occurs when revenues, accomplished through the sale of goods or services, exceed the costs incurred. A business' financial statements, when properly prepared, should show whether it has produced profits. The retention and compensation of executives is likely to be determined by performance as revealed through financial statements. Other aspects of a business' performance, such as the costs or benefits that it might create in the broader society, are likely to go unreported. Being "externalities," those costs or benefits are not identifiable within the context of a firm's financial accounting and reporting systems.

In government and nonprofit organizations, the transaction-based information that reveals their financial performance cannot reveal their accomplishments relative to efforts. If a business firm has been profitable, its balance sheet should show an increase in its assets relative to its liabilities. But if a nonprofit organization or a government agency shows that its assets have increased relative to its liabilities, its stronger

financial position could indicate that performance has been poor—e.g., that the nonprofit has not tried as hard as it should have to provide services or that a government has charged higher taxes or fees than it needed to do. The information that is vital to measure their performance is that which reveals their effects upon the recipients of their services.

In short, the financial statements of government and nonprofit organizations are inherently insufficient and incapable of reporting vital aspects of their accomplishments. To report performance for these organizations, special efforts must be put forth to identify these organizations' outputs and outcomes. Outputs are the activities done by an organization (such as students taught, gallons of clean water pumped, or miles of roadways repaved) and outcomes are the societal effects of the activities (such as jobs well performed by graduates, waterborne diseases averted, or the ease with which users transit the roadways). Even though conscientious governments and nonprofit organizations have shown that it is possible to measure and report useful information about performance, most governments and nonprofit organizations are deficient and many have not developed rudimentary, much less adequate, performance reporting systems.

STEWARDSHIP AND ACCOUNTABILITY

Performance reporting by the officials of governments and nonprofit organizations is essential to the fulfillment of their stewardship and accountability obligations. The concept of stewardship has existed for at least two millennia in western culture. The Bible in the book of Matthew describes stewardship as requiring active and faithful management by servants of the money entrusted to them by a master. The essence of the concept remains basically unchanged today. Stewardship obliges public officials to strive to deliver good value to their "masters," their fellow citizens who pay taxes and fees. The leaders of charitable nonprofit organizations are similarly obligated to deliver value to clients on behalf of donors.

Accountability is a relationship between those entrusted to lead and manage an entity and those who entrust the leaders to manage on their behalf. The concept of accountability requires that results be communicated. Without communication of results, the efficacy of organizational leadership cannot be ascertained. For government officials, this relationship is well summarized by the Governmental Accounting Standards Board (GASB) in its Concepts Statement Number 1.^[1]

Accountability requires governments to answer to the citizenry—to justify the raising of public resources and the purposes for which they are used. Governmental accountability is based on the belief that the citizenry has a “right to know,” a right to receive openly declared facts that may lead to public debate by the citizens and their elected representatives.

PERFORMANCE REPORTING HAS LONG HISTORY

The need to hold operating officials accountable for performance is not new. It is unlikely that the pyramids could have been built so well without reports being submitted on the performance of surveyors, stonemasons, suppliers, and so on. Performance reporting was practiced in President George Washington’s first administration, as is evidenced by Treasury Secretary Alexander Hamilton’s orders to the commanding officers of the new revenue cutters that they keep a regular journal of activities and submit these to the Treasury monthly.^[2]

A century later, the activities of a philanthropically supported organization called the New York Bureau of Municipal Research deeply influenced the emergence of professional public administration in America. The Bureau’s founders maintained that reporting about performance was an obligation of public servants in the interest of fostering democratic government. The best way to assure that governments will continually seek to become more efficient, they argued, is to inform citizen-voters about the performance of government relative to its costs.^[3] The influence of the Bureau was subsequently felt in several efforts to improve the performance of the federal government. Most notable among these was the first Hoover Commission in 1947. Seeking to hold administrators accountable for performance, the commission called upon Congress to adopt a performance budget approach for the federal government.^[4] Budgeting for performance remains a major theme of reformers to the present. Any serious attempt to implement performance budgeting must include performance reporting because the former is impossible without the latter.

CONTEMPORARY DEVELOPMENTS IN PERFORMANCE REPORTING

In the early 21st century, performance reporting has become a focal point of reform in both budgeting and financial reporting. In 1998, the National Advisory Council on State and Local Budgeting issued a set of recommended practices to guide budgeting in state and local governments. In its recommended practice titled “Monitor, Measure, and Evaluate Performance,” the council underscored the essentiality of performance measurement and reporting to budgeting.^[5]

Performance measures, including efficiency and effectiveness measures, should be presented in basic budget materials, including the operating budget document, and should be available to stakeholders. Performance measures should be reported using actual data, where possible. At least some of these measures should document progress toward achievement of previously developed goals and objectives. More formal reviews and documentation of those reviews should be carried out as part of the overall planning, decision-making, and budget process.

Performance reporting is now mandated by law in the federal government. The Government Performance and Results Act of 1993 required every major federal agency to set goals, measure performance, and report its accomplishments. The law mandated that every agency prepare a Performance and Accountability Report containing program performance information.

One of the obstacles to doing performance reporting in the past was the absence of professional recognition for doing it well. The Association of Government Accountants (AGA) now has two parallel programs to provide professional recognition for good performance reporting. Each recognition program uses a peer review process. For the federal government, the AGA established in 1996, in conjunction with the Chief Financial Officers Council and the OMB, the Certificate of Excellence in Accountability Reporting program (CEAR). Its purpose is to foster excellence and improve financial and program accountability by streamlining reporting and improving the effectiveness of reports.

Through this program, the AGA advises federal agencies on how to prepare integrated and user-friendly performance reports that show what an agency has accomplished with taxpayer dollars and the challenges that remain. Participating agencies submit their reports to an AGA review team for an in-depth evaluation using established guidelines. If the reports measure up to the AGA standards, the Certificate of Excellence in Accountability Reporting is awarded.

Participating federal agencies receive training by the AGA on how to prepare the report and then receive a comprehensive evaluation of their performance reporting along with detailed recommendations for improvement. In 1998, the first year of the program, three federal agencies received the CEAR Certificate. By 2003, that number had increased to 10 federal agencies, including the departments of Education and Labor, the General Accountability Office, and the Social Security Administration.

In 2003, the AGA inaugurated a program for state and local governments called the Service Efforts and Accomplishments (SEA) certificate program. The SEA program encourages those governments to effectively communicate performance to the public by preparing and issuing high-quality performance reports. Among the 20 organizations that volunteered to participate in the first year were the Oregon State University; Missouri Department of Transportation; Austin, TX; Charlotte, NC; Phoenix and Maricopa County, AZ; Portland, OR; New York City, NY; and Prince William County, VA. For generations, reformers have admonished governments to do performance reporting. The admonishments have often fallen on deaf ears. Perhaps the creation of professional recognition programs for performance reporting will encourage its future development.

GASB's SUGGESTED CRITERIA

Since its creation in 1984, the GASB has been encouraging research and experimentation in performance measurement and reporting. In 1997, GASB received a grant from the Alfred P. Sloan Foundation to support its research. Many observers expect that the board might someday initiate its due process procedures that could lead to an authoritative pronouncement that general-purpose external financial reporting for state and local governments should include performance reporting. When, and whether, this will occur is uncertain. Governmental Accounting Standards Board's research, though, has produced an important set of guidelines for doing performance measurement and reporting.

In a special report, GASB identified 16 suggested criteria to guide state and local government officials in preparing external reports on performance.^[6] The purpose of the criteria is to help officials to produce useful performance reports, ones that will enable readers to ascertain the extent to which an organization has accomplished its mission, goals, and objectives and to better understand the context in which this has been done. The GASB criteria emphasize the following:

- Identify major goals and objectives.
- Design performance reports to clearly communicate to users.

- Focus on key relevant measures to assess results.
- Clarify costs and resources used to attain results.
- Present citizen/customer perceptions of performance.
- Compare performance to past periods, targets, or other governments.
- Use consistent measures to allow comparisons over time.
- Help users understand factors affecting performance.
- Help readers to assess the credibility of reported information.
- Report performance regularly to facilitate decision-making.

ALTERNATIVE WAYS TO REPORT PERFORMANCE

It is possible to make a performance report an integral part of a government's Comprehensive Annual Financial Report (CAFR). Doing that, however, would cause much consternation over the scope of the organization's external financial audit. It is generally advisable, therefore, to clearly separate the reporting of an organization's operational performance from the financial statements that report the organization's financial performance. The primary reason for clearly demarcating the two is to avoid confusion as to whether an organization's financial auditors, in addition to their auditing activities that are related to the financial statements, are obligated to also audit the reports of operational performance. The accountants who are trained to audit an organization's finances are seldom trained to review the program evaluation activities that undergird the reporting of operational performance. Their expertise, though, is relevant to reviewing the reported costs of an organization's activities.

It is also possible to report performance within the context of annual budgets. Reporting on performance within the context of budget requests is essential to doing performance budgeting. Many governments, however, prefer to report performance in ways that are independent from both budgets and CAFR's. Seven counties and 11 cities volunteered to be charter participants in the Association of Government Accountants' Certificate of Excellence in Service Efforts and Accomplishments Reporting program. Six of the seven counties and 10 of the 11 cities chose to use a format for reporting performance that was separate from either their budget or CAFR documents. The other two governments reported their performance information within their budgets.^[7] The AGA certificate program is quite flexible, structured to accommodate whichever form of performance report

the government considers to be its primary report. The variation in the reporting methods used by these governments suggests that leeway should be provided to enable governments to tailor performance reports to their specific situations.

ENSURING CREDIBILITY OF PERFORMANCE REPORTING

Governmental Accounting Standards Board researchers conducted a series of focus group programs with citizens in several locales. The participants indicated that they want performance information to be independently verified. In its suggested criteria for performance reporting, GASB emphasizes the importance of assessing the credibility of the reported information. The Government Finance Officers Association has stressed the need to verify performance information and has indicated that internal auditing procedures should be sufficient.

Standards for auditing performance reports are enumerated by the U.S. Government Accountability Office in its “Yellow Book,” formally titled *Government Auditing Standards*. The internal audit staffs of state governments and larger local governments should know how to use the Yellow Book standards to review the credibility of performance reports. Small governments, though, often lack significant internal audit capacity. For them, other means need to be explored. Independent citizen review boards and the AGA’s certificate review process can be used to provide an informed opinion about the credibility of the information reported about performance.

Whatever the means used to assure credibility of performance reports might be, one thing about performance reporting should always be remembered. Ultimately, the most important users of performance reports are the citizens who hold officials accountable at the ballot box. Providing credible information about performance to citizens strengthens democracy.

Performance-Based Budgeting

Judith R. Brown

*Planning, Research and Evaluation Division, Governor's Office of Planning and Budget,
Atlanta, Georgia, U.S.A.*

INTRODUCTION

What benefits do citizens realize from their investment in government? We pay taxes to fund government services; but how can we be sure the services have their desired impact? Over the past century, expectations for government budgeting, management, and accountability have shifted from controlling resources to measuring the public benefit derived from using the resources. Although performance-based budgeting promises to be a rational, systematic way to link funding to program effectiveness and efficiency, a greater promise may lie in its potential for improving government policy making and management.

DEVELOPMENT OF PERFORMANCE-BASED BUDGETING

Traditionally, funding for public agencies has been based on previous years' expenditures and activities. While public policy and program impact are discussed, the emphasis of the budget process is control of inputs and activities. However, the concept of linking performance to funding is not new. One of the earliest calls for performance measurement was a recommendation of the Taft Commission on Efficiency and Economy's in 1912:

In order that he [the administrator] may think intelligently about the subject of his responsibility he must have before him regularly statements, which will reflect results in terms of quality and quantity, he must be able to measure quality and quantity of results by units of cost and units of efficiency.^[1]

Since then, numerous strategies to link program funding to performance have been implemented and, for the most part, discarded. Three recent strategies were precursors of performance-based budgeting (PBB): Planning Programming Budgeting Systems (1965), Management by Objectives (1973), and Zero-Based Budgeting (1977).

While most governments that had adopted these strategies reverted to incremental budgeting, a few, mainly local governments, continued the effort to link

performance to program funding. As early as 1973, Sunnyvale, California, began adopting comprehensive performance planning, measurement, and budgeting.^[2] Gradually, other state, county, and municipal governments followed Sunnyvale's lead. The federal government joined the trend with the enactment of Chief Financial Officers Act of 1990^[3] followed by the Government Performance and Results Act of 1993.^[4] Both Acts mandated that federal agencies collect and report performance measures for use in the budget process. In 1994, the Government Accounting Standards Board published Concepts Statement 2, which promotes the use of performance measures in state and local financial reports.^[5] By 1999, the federal government, myriads of county and city governments, and 49 of 50 states had initiated some form of PBB.^[4,6-8]

COMPONENTS OF PERFORMANCE-BASED BUDGETING

Performance-based budgeting (PBB) links the results of program activities to budgeting and policy making. It moves the budget process away from "who gets how much" to "what benefit is derived for how much." Generally, a PBB will include six primary components: program; program purpose; goals; performance indicators; performance targets; and explanatory data. [Table 1](#) provides definitions and examples of each component including five types of performance indicators.

BENEFITS AND CHALLENGES

Performance-based budgeting (PBB) has been in existence long enough to identify key benefits and challenges to its continued use and contribution to government management and policy making. Some of these benefits and challenges are discussed in the following paragraphs.

Defining Purpose and Goals

To some extent, the first tasks in developing a PBB can be among the most challenging and useful. Articulating

Table 1 Components of performance-based budgets

PROGRAM: A systematic set of activities undertaken to accomplish a valued goal

Example: Teen Pregnancy Prevention Program

PROGRAM PURPOSE: Why the program exists; who or what it is to impact

Example: Reduce the teen pregnancy rate through education and services

GOAL: A broad statement of what will happen if the program is effective

Example: Education program participants will not become pregnant before age 20

PERFORMANCE INDICATOR: Short-term, quantified measure of progress toward a goal

INPUT MEASURE: Resources applied to the program

Example: Number of staff allocated to the education program

PROCESS MEASURE: Units of activities and services provided

Example: Number of workshops offered

OUTPUT MEASURE: Incremental change resulting from program activities

Example: Number of teens aged 14–17 completing the program

EFFICIENCY MEASURE: Ratio of input to output; Cost of unit of service

Example: Percentage of program participants completing the program

OUTCOME: What specifically will happen if program is successful

Example: Pregnancy rate for participants 3 years after program completion compared to similar teens not participating in the program

PERFORMANCE TARGET: Unit of improvement or difference

Example: Program participants: three fewer pregnancies per 100 than non-participants.

EXPLANATORY INFORMATION: Clarifying Information; data limitations; disclosures

Example: The characteristics of 15,000 program participants were matched with a comparison group of 2500 non-participants

a program's purpose and its primary goals can require considerable effort on the part of program management. Program staff must focus on what program activities are to accomplish rather than the activities. This can be difficult, as it is not uncommon for agency personnel to become so involved with routine process that they begin to think the activities *are* the program's purpose. This effort can be complicated by ambiguous program mandates and evolving expectations. The development of outcome-oriented

goals forces program managers to create a specific picture of what program success looks like. This gives precise definition to often vague mandates. While the process can be trying, the results can be useful to the policy makers (who may have conflicting views of the program's purpose); the public (who can develop significant misconceptions and unreasonable expectations of the program); and program management (who may realize some of their efforts have been misdirected to activities that do not support their program's purpose).

Developing Performance Indicators

Performance indicators provide program staff, policy makers, and the public with an overview of how well government is addressing public concerns. Because they are short-term measurements, the indicators not only disclose program effectiveness and efficiency but also allow program managers to monitor internal performance. Performance indicators are the linchpins of PBB. In keeping with their importance to PBB, they also are the most problematic.

Although emphasizing the need to measure program results, most PBBs report few outcomes, relying instead on input, process, and output indicators. This is because outcomes are difficult to measure. Sometimes, program staff work so hard improving process that they forget what the processes are to accomplish. While secure in conceptual goals, others are unable or unwilling to translate those goals into measurable indicators. All too often, programs assert they have no responsibility for their outcomes. In their concern over the impact of external factors on effectiveness, they abdicate any responsibility for program results. In other instances, there are legal, logistical, or practical issues that impede the collection of outcome data. Occasionally, no one has found a good way to measure a specific impact. And, often, programs have never collected outcome data, and to modify their information systems would be prohibitively expensive. With the option of reporting other types of performance indicators, many programs avoid reporting on outcomes and assume that if they are effective and efficient in providing services, there is no need to test whether these services achieve desired results.

Identifying Performance Targets

Initially, PBB was promoted as a way to reward programs that performed well and to penalize those that did not. While a few governmental units still adhere to this premise, most have discovered it is simplistic

and counterproductive. PBB had been thought to provide definitive answers on program efficiency and effectiveness. Many have found that, instead, PBB provides more questions. What does it mean when a program has not met its performance target? Is the program strategy ineffective? Is management inefficient? Did something external to the program adversely impact results? Is funding insufficient to achieve success? Without additional research to answer these questions, policy makers lack enough information to take action. Perhaps the most beneficial way to view performance indicators are as tools to diagnose strengths and weaknesses in governmental effectiveness that require follow up to determine the causes.

Although many users take this diagnostic approach, some programs fear that failure to meet a performance target will result in punitive action. Programs must set performance targets several years in advance. To compensate for unforeseen deterrents to performance, some programs understate performance targets to avoid sanctions if they cannot be met. Thus, the targets cease to be inspirational benchmarks and instead become symbols of future mediocrity.

Reporting Useful Data

Issues relating to the adequacy of data are inherent to any type of record keeping and reporting. Many information systems are depositories for easily collected, but not necessarily useful, data. Other times, the data are meaningful, but due to resource constraints or the methods in which the data are collected, there are likely to be undetected errors, omissions, and delays. While some users, for example, the states of Texas and Louisiana, have established systems for independently verifying PBB data, most rely on programs to monitor the integrity of their information.^[9]

Data must also be presented in context. To report process data as though they were outcome data gives the PBB user a false picture of what is measured. Labeling performance indicators by type helps prevent this problem. Sometimes, however, it is necessary to use one type of measure as a “proxy” for another. Other times, flaws in data collection overstate or understate performance, and some data is too expensive to collect. While all of these data concerns are significant, this does not mean that governments should stop collecting data on performance. It means, however, that data limitations should be identified and fully disclosed. Furthermore, because program performance may vary significantly from year to year, multiple years of performance data should be shown to allow the identification of trends.

Effective reporting also requires that the users of the PBB be aware of the reliability and implications of the data reported therein. This requires explanatory data that discloses data limitations and, when necessary, spells out what the reader should surmise from the information presented. Because factors not within the program’s control can cause actual performance to vary significantly from year to year, it is important to present several years’ of information.

Presenting all the PBB data on purpose, goals, performance, and disclosure has proven to be a daunting task. An official in Arizona, one of the pioneers of performance reporting, commented, “we collect so much information at the agency, program and sub-program level that the state is overwhelmed We are data rich, but insight poor.”^[8] This is not an uncommon experience. To address this situation, most PBBs are now more concise, including only key programs and indicators. The State of Georgia has elected to report only outcome data, reasoning that it does not matter if programs are efficient or well run if they are not successful in addressing the problems they were created to solve.^[10]

CONCLUSION

Performance-based budgeting has been advanced as a way to link performance to funding. However, it is unclear the degree to which federal, state, and local governments have been able to do so. The dream of accurately determining the cost of a unit of result is far in the future. And, upon reflection, the concept of rewarding “good performance” and penalizing “bad performance” makes little sense. However, many policy makers and public administrators are finding PBB more useful than imagined. Performance based budgeting is now being reframed as “Managing for Results.” Utilizing program purposes and goals to articulate public policy and using performance data to diagnose problems, identify successes, and improve government services has great promise. Performance-based budgeting has not been proven to be a “silver bullet” that drives the funding of public programs. However, it may be of even greater value in articulating public policy, informing the budget process, improving public services, and making government more accountable to the citizens it serves.

Policy Change

James L. True

Department of Political Science, Lamar University, Beaumont, Texas, U.S.A.

INTRODUCTION

Policy change refers to a significant departure from past policy, which may be defined as whatever decision-making organizations chose to declare and implement. Policy changes have enduring qualities, by which they can be distinguished from routine decision-making. Examples could be drawn from business, religious, or other organizations, but public policy and public administration refer to what governments say and do over time, and the examples of policy changes that follow are drawn from U.S. national government policymaking.

DIFFERENT PERSPECTIVES ON GOVERNMENT POLICY CHANGE

What constitutes significance in government choices may depend upon whose ox is being gored. An alteration in government policy that has direct personal effect may be seen as significant, while a similar alteration that affects someone else may not. But in a larger sense, what one sees as significant in new government decisions depends upon one's overall perspective on government policymaking and on the societal consequences of various policies over time.

Government policy changes have historically been viewed from at least four different theoretical perspectives on collective decision-making. They are the perspectives of comprehensive rationality, incrementalism, organizational (or cybernetic) theory, and cognitive decision theory. Each of these theories is briefly reviewed below, along with a more recent approach called punctuated equilibrium theory.

Comprehensive rationality (sometimes called positive political theory or formal theory) is a major framework for much policy research, but it has not been very helpful in distinguishing between routine government decisions and ones significant enough to be seen as policy changes. The contribution of this framework to studying policy change is to emphasize the purposefulness in individual and collective decision-making. Choices are analyzed based on individual preferences and intentions. Although it is clearly possible for policymakers to want one thing and to achieve something else, this quality of purposefulness pervades the study of policymaking.

Comprehensive rationality usually sees government as a single entity that seeks to maximize utility and control risk. Government adaptively changes public policy in response either to new demands for public goods and services or, more generally, to any important change in the external environment. (One variant of this perspective analyzes policy change with a principal-agent model, wherein the government is the agent of the public or, alternatively, where the bureaucracy is the agent of congress and the president.) But comprehensive rationality often draws no clear distinction between routine decisions (essentially policy continuation) and changes significant enough to be called policy changes.

Incrementalism essentially focuses on policy continuation, but important policy change can occur in the form of long-term program growth or contraction. Incrementalism sees government policy ameliorating whatever problem is presented for decision, first by accepting or ignoring much of what has gone before and second by making marginal adjustments to the policy under consideration. From the incrementalist perspective, most policy or issue areas (the internal environment) will largely be accepted as is, with little or no policy change. Some policies will be considered and incrementally revised, and a series of marginal increments (or decrements), if repeated enough times, can result in significant change.

Cybernetic theory distinguishes between routine and non-routine changes in policy. This theory sees government as an adaptive machine—a system that simplifies its decision- and policy-making tasks by ignoring much of the external environment. The machine survives by dealing with a circumscribed set of inputs and by invoking simplified decision rules or standard operating procedures. From this perspective, most decisions are routinely handled without a major change. On occasion, however, an input outside of expected channels will invoke a second level of responses that can result in substantial changes.

One popular form of cybernetic or organizational theory is institutionalism. Institutionalism (and later neoinstitutionalism) stressed the importance of internal organizational arrangements and rules in producing public policies. Yet institutionalism does not fully explain why the same government institutions sometimes react to a particular input with little or no policy change and, at another time, they react to a similar input with a major policy change.

Cognitive theory is something of a special case insofar as policy changes are concerned. Cognitive theory arises from cognitive psychology and generally sees government decision-makers as adaptively or maladaptively changing policy only when external changes in the environment capture their attention. Changes in the objective circumstances can be ignored for some time, when they run counter to what decision-makers have come to expect. From this perspective, it is not just changes in the external environment that generate policy change but the decision-maker's recognition and acceptance of those changes and his or her internal responses to them. Thus, cognitive theorists are concerned with both the external environments and the perceptions and cognitive mechanisms of the decision-maker.

Punctuated equilibrium theory attempts to integrate the incremental, organizational, and cognitive perspectives into a view that sees government as an interactive system of at least two different levels of government decision-making. The interactions between these two internal levels and between the system and the external environment produce both periods of stasis when individual policies do not change and periods when individual policies do change, either incrementally at one level of government or radically at the other level. U.S. government institutions are seen as conservative in the sense that it usually takes a series of collective agreements before a policy can be changed. As a control against tyranny, the framers of the constitutions sought a separation of independent institutions, each branch of which required some cooperation from at least one other branch to make new policy. Yet, separate branches in a federal system also provide multiple venues from which policy changes can be initiated.

From the punctuated equilibrium perspective, the growth of the national government in the twentieth century augmented constitutional sharing of powers between branches and between national and state governments by creating subsystems, "iron triangles," and issue networks, in order to handle the greatly increased tasks assigned to these governments. Policymaking within subsystems features a politics of adjustment, with incremental change resulting from bargaining among interests and marginal adjustments to changed circumstances. The growth of modern society and the expansion of technology further complicated policymaking by creating a variety of new issues and new ways of looking at old issues. Separate branches, multiple levels, and overlapping jurisdictions create a complex interactive system of government. Once a subsystem has garnered policymaking authority in an issue area, public mobilizations are often required to overcome the inertia of vested interests and existing arrangements. From this perspective then, issue definition is critical for attracting the attention of

policymakers outside of a policy monopoly or for mobilizing larger public involvement.

Punctuated equilibrium theorists expect policymaking to produce two sorts of changes: 1) very small changes when policymaking is in the hands of a policy monopoly or stalemated as two fractions of a subsystem vie for control and 2) very large changes after the issue is on the active agenda of the top levels of the national government and that level chooses to rebalance the problems, solutions, and political pressures upon it. The first sort of change is viewed as equilibrium and the second sort as policy punctuations. The first sort would be defined here as policy continuation and the second sort as policy change.

PORTRAYING LASTING AND PURPOSEFUL CHANGES

Although measuring policy changes over time presents several difficulties, longitudinal records of government spending can be used, for they offer the advantages of an easily understood measure (dollars) and an authoritative historical record (the annual budgets of the U.S. government). Some policies and changes to them have little impact on national spending, but most policies require resources to implement them, and the historical record of that resource use can provide a picture of policy changes over time. These examples graph the historical spending records for two representative national purposes: 1) support for national parks and other recreational resources and 2) national funding of medical insurance for the aged. The policy process and the spending for the first purpose are categorized as discretionary, while those for the second purpose are categorized as mandatory. The data for these figures are taken from the *FY 2007, Budget of the United States Government*, "Historical Tables." They trace U.S. Treasury payments for "recreational resources" (budget subfunction 303) and "Medicare" (budget function 570). The effects of inflation have been removed from the series by converting the annual figures to constant FY 2005 dollars, through the use of the chained gross domestic product deflator in the historical tables.

GOVERNMENT SUPPORT OF RECREATIONAL RESOURCES

National government spending for recreational resources is discretionary. The budget requests for the National Park Service and other pertinent programs in this subfunction are scrutinized by the Department of the Interior, are reviewed by the Office of Management and Budget, are presented as part of the President's annual budget, and are reviewed by Congress,

which annually appropriates specific levels of funding for them. Policy changes in this discretionary area include decisions concerning the nature and size of park lands and the proper level of funding for each year.

Fig. 1 indicates that annual national government spending for “recreational resources” grew incrementally through FY 1977. That is to say, annual executive and Congressional reviews of the budget proposals for recreational services resulted in successive years of incremental growth. In FY 1978, there was a policy change from President Carter’s ambitious land heritage initiative, and there was another change in FY 1982 when the Reagan administration chose not to support that initiative at the same level. Later, Congress refused to make the decreases proposed in the executive budget submission for FY 1990. Instead, Congress passed the Emergency Wetlands Resources Act (its own policy change in this area), after which outlays moved to a new level. In FY 1999, Congress agreed with Clinton administration on the use of government oil and gas revenues from the outer continental shelf to fund a Land and Water Conservation Fund that financed the acquisition of new park lands, green spaces, and other initiatives. The budgets of the Bush administration feature park maintenance and improvements rather than expansions, and policy changes again appear to be incremental in this area, although remaining at a relatively high level. Policy changes occurred in this small discretionary area, either as a result of incremental increases reiterated over a number of years or as a result of program initiatives and reassessments that had purposeful and lasting effects.

GOVERNMENT SUPPORT FOR MEDICAL INSURANCE FOR THE AGED

National government spending for Medicare is categorized as mandatory. Medicare is an entitlement to a nation-wide health insurance program for people aged 65 and over and for certain people with disabilities.

Fig. 1 Outlays for recreational resources. (From Tables 3-2 and 10-1 of the FY 2007 *Budget* “Historical Tables.”)

Medicare entitlements are established by public law and generally are funded without additional Congressional deliberations. A policy change for this entitlement requires a change in program law as to who is covered or what benefits will be funded. Medicare consists of three parts: hospital insurance (Part A); supplementary medical insurance (Part B); and voluntary prescription drug coverage (Part D). The total spending for Medicare consists of the sum of the annual cash outgoes of both the Health Insurance and Supplemental Medical Insurance trust funds. Voluntary prescription drug coverage did not begin until January 1, 2006.

The initiation, expansion, contraction, and latest expansions of Medicare illustrate the purposeful and lasting qualities of policy changes. Medicare was created by the Social Security Amendments of 1965 and expanded in 1972 to include certain people with disabilities. Fig. 2 portrays the long-term growth in Medicare spending, driven largely by increases in the covered population and by expansions in medical technology, treatments, and costs. The purpose of the 1965 amendments was to provide medical insurance support for those aged 65 and over. The growth of the eligible population and the growth of Medicare coverage within that population occurred without a change in that original purpose. This expansion of government spending for Medicare can best be analyzed as a continuation of the policy changes of 1965 and 1972, although the steady expansion in Medicare spending illustrates how repeated incremental growth can result over time in significant program expansion.

Government did change Medicare policy in the Balanced Budget Act of 1997 (BBA of 1997 in P.L. 105-33). BBA of 1997 sought to decrease Medicare spending both to improve the financial viability of its trust funds and as part of other reductions aimed at balancing the federal budget by 2002. Medicare had some special urgency in that the 1996 report of the trustees of the Federal Health Insurance Trust Fund had projected that, without changes, the fund would be in deficit in 2001. The biggest budget savings in BBA of 1997 came from reducing Medicare payments

Fig. 2 Annual cash outgo for Medicare. (From Tables 10-1 and 13-1 of the FY 2007 *Budget* “Historical Tables.”)

to doctors, hospitals, nursing homes, home health agencies, and managed care plans. When the payment reductions proved to have larger impact than expected (and under pressure from a variety of interest groups), Congress rescinded some of the reductions with the Balanced Budget Refinement Act of 1999 (BBRA of 1999 in P.L. 106-113).

The historical cash outflows in Fig. 2 indicate that Medicare spending leveled off after the 1997 Act and resumed its increases after the 1999 act. Incremental Medicare expansions were underway even as policy changes on payment reductions were enacted and rescinded. Separate provisions of the two budget acts and the Benefits Improvement and Patient Protection Act of 2001 (incorporated in P.L. 106-554 enacted in December 2000) expanded beneficiary access to preventive-care services. In addition, the Medicare Modernization Act of December 2003 (P.L. 108-173) would likely lead to new annual increases. However, they are not part of this historical spending record, because Part D prescription drug coverage did not begin until January 1, 2006.

Policy changes of a lasting and purposeful nature occurred and may occur again even in the policies and spending for this very large mandatory entitlement program.

POLICY CONTINUATION AND POLICY CHANGE

Theoretical perspectives on policy- and decision-making provide bases for characterizing changes to policy and for distinguishing between the routine nature of policy continuation and the lasting and purposeful nature of policy change. Comprehensive rationality invites a focus on preferences and purposes and looks to the external environment as the impetus for change. Incrementalism emphasizes the importance of an organization's internal environment and notes that government usually responds to external pressures for change with marginal accommodations. Modest increments (or decrements) must be continued over a long period of time if one is to recognize them as significant. Cybernetic theory also focuses on internal processes and the organization's structured relationship with its environment. It also notes the routine nature of most government decision-making and policy, but it adds the possibility of a second level of larger government responses when the circumstances are right. Cognitive

theory notes that decision-makers are not neutral to external circumstances. They accept some external inputs and ignore others. Analyzing policy changes will require some understanding of both external and internal environments, with special emphasis on the attentiveness and attention of the decision-maker. Punctuated equilibrium theory agrees on the importance of policymaker's attention and adds to it the importance of public mobilizations and multilevel government institutions. The result is its view of government as a complex interactive system. Objective changes in the external environment do not automatically generate appropriate government responses. They must be attended to and interpreted before they can energize government policy changes, and there is no guarantee that they will not be ignored. Policymaking at the subsystem level of the national government involves processes and politics that produce policy continuation or at most incremental changes. Policymaking at the top levels of the national government involves processes and politics that can produce significant departures from past policy—policy changes that are likely to have lasting and purposeful effects on the environments.

Policy Design

Anne L. Schneider

College of Public Programs, Arizona State University, Tempe, Arizona, U.S.A.

Helen Ingram

School of Social Ecology, University of California, Irvine, California, U.S.A.

INTRODUCTION

Policy design refers to the content and substance of public policy—the tools, instruments, and other features or “architecture” of policy. Just as a city has a design, so also do public policies—whether constitutions, statutes, governmental pronouncements, agency guidelines, or practices of implementers. Moreover, just as a city’s design can be characterized along many different dimensions, so too the description and analysis of policy design must encompass multiple dimensions.

Governments at all levels have many choices of tools or instruments with which they carry out their responsibilities. These responsibilities all fall within the broad framework of what we call public policy: allocating goods or distributing costs, regulating, extracting resources, persuading, controlling, listening to, and leading the population. The choices governments make in the details of policy designs, however, have long-term effects on politics, democracy, justice, and citizenship.

APPROACHES TO THE ANALYSIS OF POLICY DESIGN

The study of policy design traces to the very beginnings of the study of public policy and administration in the sense that the content and substance of public policy has always been central to these fields of study. The complexity of policy content, however, resulted in the early attempts to study policy design focusing mainly on case studies, without a common framework of description or analysis. More recent work attempts to identify systematic ways of describing policy designs that will enable researchers to compare designs across different policy arenas, and to compare the same kinds of policies across different countries or time periods.

The importance of policy instruments was highlighted by Dahl and Lindblom as early as 1953 when they noted that “this process [the invention and innovation in social techniques] is perhaps the great political revolution of our time.”^[1] They attributed the

capacity of government to avoid having to make stark dichotomous choices between socialism on the one hand and capitalism on the other to the proliferation of techniques that blurred the lines between these seemingly absolute dichotomies.

Most of the initial efforts attempted to describe policy content in broad strokes. Dahl and Lindblom^[1] posited five dimensions they believed could capture differences in designs: private to public; compulsory to informative; direct to indirect; compulsory to voluntary membership; and prescriptive to autonomous within the hierarchy. Ripley’s work^[2] cast the history of the United States in terms of three broad types of policy designs: subsidies (such as the Louisiana Purchase and the homestead act); regulation (of railroads, business, labor); and the most recent, manipulation, which included efforts to reduce the gulf between the indulged and the deprived. Bardach^[3] suggested four types: prescription, enabling, incentives, and deterrence.

Lowi^[4] is widely acknowledged as being the first scholar to propose a way of characterizing policy content that sparked theoretical and empirical development. His work emphasized that the study of policy design should not focus exclusively on why different kinds of designs emerge, but in fact, should recognize that policy content is an important cause of politics itself. The possibilities offered by policy, Lowi contends, create the arena in which politics is played out, with different types of policy-producing variations of pluralist or elitist politics.

Lowi’s typology features two dimensions: the extent of coercion (i.e., whether benefits or burdens are being distributed); and whether the policy is directed at specific groups or whether it consists of rules that affect the more general environment. This fourfold typology produces four types of policies: distributive, regulatory, redistributive, and constituent. His theory suggested that distributive policy, which is the classic pork barrel in that benefits are being distributed to specific groups, will produce a form of particularistic politics with agencies or bureaus, the members of congressional committees and narrow clientele groups benefitting through log-rolling and bargaining. Regulatory policy, which imposes costs that impact many

groups, will produce classic pluralist competition with various interest groups vying to gain regulations that benefit them or inflict costs on their competitors. The politics that results is often partisan, with contests between different coalitions of interest groups played out in congressional floor debates that are highly contentious. Redistributive policy, he believed, would create a form of elitist politics in which the President and close advisors, often including leaders in either business, labor, or other broad sectors of society, would formulate a policy and build support for it. This support often was built on the basis of appeals to class or economic divisions. The policies that were formulated would simply be ratified in the congress.

James Q. Wilson^[5] also developed a typology for policy that offers an explanation of how policy content produces different patterns of politics. The two dimensions in his typology are whether benefits or costs are being distributed and whether the recipients are concentrated or dispersed. Majoritarian politics, he says, will ensue when benefits and costs are both widely distributed over a large number of people. The rationale here is that all will have about the same incentive to pay attention to politics. Interest group politics will emerge when benefits are concentrated on only a few, and costs are distributed among only a few (such as regulations that favor workers at the expense of business or vice versa). His reasoning is that the motivation of both sides will be about the same and both will mobilize to protect their interests. Clientist politics is when elected leaders distribute favors to small and concentrated groups (who then are highly motivated to protect such favors), whereas costs (through taxes) are broadly dispersed leading to no particular motivation to pay attention. Welfare policy is the main example of this type, and Wilson argues that government will always expand its clientist policies because they offer such high payoffs for elected leaders. Entrepreneurial politics occur when small portions of the population pay the costs to benefit large numbers of people. Taxation policies, for example, that impose especially heavy burdens on the rich and distribute the funds widely such as to education or social security, are examples. Wilson argues that government also will expand its entrepreneurial politics far more than is warranted because so many are motivated to continue gaining benefits at the expense of so few.

There are some difficulties with both of these typologies. Lowi's framework has sparked considerable research, but empirical studies are difficult because almost all policies contain elements of more than one of the types. There are almost no pure types. Wilson's framework has this same problem, but in addition, has over time been shown simply to be wrong in many respects. Welfare policy, which he believed would continually expand, has not expanded but retracted.

Federal policy has reduced (not increased) the taxation rate paid by the richest segments of society.

While Lowi and Wilson were interested in the broad relationship of policy content to types of politics, other researchers focused on fleshing out notions of policy elements and tools of government. In 1985, Stephen Linder and Guy Peters characterized policy design analysis as middle-level theory that was a mix of three dimensions: a theory of causality, evaluation, and instruments.^[6] David Boborow and John Dryzek^[7] concentrate on the process through which designs are constituted and legitimated. Their aim is to foster a broad dialogue among different design perspectives on issues such as instrumental and communicative reason so that the design process is open and democratic. Another group of researchers addresses in great detail the advantages and disadvantages of the adoption of certain specific policy instruments or tools. A volume edited by Lester Salmon^[8] addresses a variety of policy tools including grants, tax expenditures, loan guarantees, contracting, public information, and other instruments. The concern of many authors in the tools field is that widespread policy designs embodying contemporary notions of decentralization and devolution may have unexpected and perhaps negative effects.

The understanding of policy design and development of theories of design have been advanced recently by scholars who factor into the analysis the power and social constructions of policy participants, particularly target populations. The basic argument is that variation in designs can be at least partly explained by differences in the power and social construction of target populations and other interested parties in the policy space.

TARGET POPULATIONS, SOCIAL CONSTRUCTIONS, AND THE ELEMENTS OF DESIGN

The symbolic aspects of public policy have long been recognized in the study of politics, but their incorporation into studies of public policy generally and policy design specifically has been more recent. Building on the work of Murray Edelman,^[9] several policy scholars have emphasized the central role played by policy images, the way issues are framed, and the social construction of target populations, events, or the "items" of public policy.^[10-18] What these approaches have in common is the incorporation of meaning, interpretation, symbolism, and social constructions into the description of policy design and into theories of both the causes and consequences of variation in policy design.

Schneider and Ingram^[15,16] posited that policy designs—including constitutions, statutes, agency

guidelines, and everyday practices of implementers—almost always contain a set of common elements including:

- Goals or problems to be solved.
- Target populations (those impacted directly or indirectly by the policy).
- Allocations of benefits or burdens (both material and symbolic).
- Tools (the devices used to insure the behavior needed by the policy).
- Rules (who is to do what, when, with what resources, to whom, with what constraints).
- Implementation structures (agencies, contractors, street-level case workers).
- Rationales (the logic, causal arguments, rhetorical devices, data).
- Underlying assumptions (implicit or explicit, agreed upon or contested).

Each of these has multiple dimension. For example, tools can be conceptualized in terms of their underlying behavioral assumptions producing several “types” of tools: positive incentives, negative incentives, force, information, capacity building, authority (pronouncements without penalties); persuasion; and learning.

Building from a framework of design elements, Schneider and Ingram developed a two-dimensional typology of target populations consisting of the political power resources of target groups and other interested parties (ranging from high to low) and the social constructions of target populations and other interested parties (ranging from positive to negative) (Fig. 1). The policy space created by examining political power and social constructions produces four “types” of target populations (although these are best thought of as a continuous rather than categorical characterization). *Advantaged* populations are those that have considerable political power resources and are positively constructed, usually as “deserving,” or “good.” Examples include business, the middle class, family farmers, and senior citizens. *Contenders* have political power resources to use but are negatively constructed, often as “greedy” or “undeserving” in some way. Examples of these groups include gun owners, the rich, and CEOs of large corporations. *Deviants* is the label given to those who have no legitimate forms of political power and are negatively constructed as dangerous and violent. Examples include criminals, terrorists, flag burners, and gangs. (Terrorists, of course, have the power to generate fear and take the lives of civilians; but by definition, the power of

Fig. 1 Power and social constructions of target populations.

terrorists is not legitimate political power in the usual sense of that term.) *Dependents* are persons or groups with little or no political power but who have generally positive constructions, such as “good, deserving, people,” although “helplessness” is also a common characterization of these groups who include children, mothers, the poor, homeless, and so on.

The theory of target populations and policy design that we propose is that each of these segments of the policy space will often be characterized by common types of design elements. Under conditions of pluralist or hyperpluralist political institutions, much can be learned about the characteristics of rationales, implementation structures, rules, tools, goals, and allocation patterns if one focuses on which type of target population the policy (or segments of it) is directed toward. For example, benefits are more likely to be oversubscribed to advantaged populations and undersubscribed to deviants, whereas punishments or costly regulations are more likely to be undersubscribed to advantaged and oversubscribed to deviants. The tools for delivering benefits to the advantaged typically will focus on capacity building (such as subsidies, entitlements, free information, and outreach programs), whereas the tools for delivering burdensome regulations to this same group are more likely to focus on self-regulation, learning, positive inducements, standards and charges, and only rarely, sanctions. Sanctions or regulations are likely to be imposed only when needed to protect one group of advantaged from another group of equally advantaged people. Tools for delivering benefits to dependents are expected to be income-tested subsidies in which the clients must establish their own eligibility, whereas tools for delivering benefits to advantaged groups are expected to be broad-based and not require means testing (social security, e.g., or farm subsidies). Rationales are expected to differ. When benefits are delivered to advantaged groups, rationales usually will be justified on the grounds of important national interests or an efficient means to the goal, whereas benefits to dependents are more likely to be justified on justice grounds such as equal opportunity, need, or fairness. Benefits to deviants generally do not occur unless required by courts on the grounds of fundamental rights or human decency.

This aspect of the theory has produced a significant amount of empirical research that generally supports the contention that social constructions of target populations are centrally implicated in the types of designs that emerge (or whether policy will be adopted). Donovan,^[19–21] e.g., characterized target populations of persons with HIV/AIDS in terms of how they contracted the infection and found that allocations for HIV/AIDS research disproportionately allocated funds to those contracting the disease who were

“advantaged” (medical workers, health professionals, people who got it through transfusions) compared to those who were not so “innocent” (i.e., drug users, homosexuals). Analysis of the generosity of government subsidies varies quite directly with the social construction and power of the target populations when one compares corporate welfare, e.g., with aid to those who are poor.

Other studies have shown that the manipulation of the social construction of target populations is a central aspect of discursive strategies used in legislative policy making. Jensen^[22] shows how some types of veterans but not others came to be eligible for veterans pensions. Sidney^[23] examines the ways in which a Black middle class was separated from “urban rioters” in debates about eliminating discriminatory practices in housing so that benefits could be provided to the former and denied to the latter. Studies of immigration policy document that underlying racist motivations have produced negative constructions as “undeserving” for many minority groups leading to highly restrictive immigration policy.^[24,25] In a similar way, federal drug policy provides a much heavier penalty for crack cocaine than for powder cocaine, arguably because the former is used mainly by inner-city Black males and the latter by White middle-class professionals or athletes. The elimination of welfare as an entitlement owes much to the ability of moral entrepreneurs who have depicted welfare recipients as “welfare queens” or as unmarried, immoral teenagers who have children so that they can collect a welfare check.

Following the ideas contained in the Lowi and Wilson theories, we also have proposed that policy designs produce politics. Social constructions become embedded in public policy, producing messages to target populations that are interpreted and internalized with significant implications for political participation, attitudes toward the state, and citizenship. Mettler^[26] documents that the GI bill was a crucial factor in the political participation of veterans. Soss’s^[27,28] empirical research on welfare compares the impacts of two very different policy designs: social security disability policy and Aid to Families with Dependent Children. His analysis presents strong evidence that differences in these designs have produced critical differences in trust of the state, efficacy, inclination to vote one’s interest in elections, and overall participation patterns.

Theories of policy change also have begun to incorporate the importance of image, symbolism, and social constructions of policy participants in understanding whether policy change will occur and whether it will be incremental or sudden. Baumgartner and Jones,^[13] e.g., in their analysis of punctuated equilibrium theories take into account the policy images and the social constructions of target populations.

CONCLUSION

The central contention of scholars who focus on policy design is that the content and substance of public policy is as important to study as the processes that produce policy. Furthermore, the policy design scholars emphasize that process cannot be well understood without a careful analysis of the product that has been produced. The power, social construction, and ideas that drive policy designs become embedded in the design elements. The goals, problem definitions, rules, tools, rationales, and implementation structures all reflect the dynamics of the policy production process. Policy designs also have significant impacts on target populations, others interested in the policy arena, and the general public. Differences in policy designs have been linked to important differences in attitudes about the state, conceptions of citizenship, and levels of political participation. The study of policy design offers rich potential for understanding how American democracy works, who benefits, and who suffers.

Policy Diffusion

Karen Mossberger

Department of Political Science, Kent State University, Kent, Ohio, U.S.A.

INTRODUCTION

“Diffusion is the process by which an innovation is communicated through certain channels over time among the members of a social system,” according to Everett M. Rogers, one of the pioneers in diffusion research.^[1] Rogers defined the diffusion process as a form of social change, based on communication, ideas, and information.^[1] Diffusion research has been undertaken in a number of social sciences and professional disciplines, such as sociology, geography, communications, economics, organizational studies, business, and education. *Policy diffusion* involves the spread of policy ideas across political jurisdictions and may occur within a single country or across national borders.

DIFFUSION AMONG THE AMERICAN STATES

Within the United States, the primary focus has been policy diffusion among the states rather than local governments. Jack Walker's^[2] seminal article, “The Diffusion of Innovations Among the American States,” made several important arguments that largely set the research agenda for the following decades. He contended that there was an identifiable league of more innovative states, that there were regional patterns of emulation, that state and professional organizations provided a network to communicate policy ideas and information, and that policy diffusion represented a form of “bounded rationality” that reduced the costs of adopting new policies. The hypotheses set forth by Walker were both amplified and challenged in subsequent studies. Among the topics that have been explored are innovativeness as a characteristic of states, alternative determinants of diffusion, policy variation, sources of diffusion, and processes.

Timing of Adoption

Consistent with diffusion research in other disciplines, policy diffusion studies have often tried to explain the difference between pioneers and laggards, or between early and late adopters of an innovation. This approach defines “innovativeness” as a trait of adopters. Examining 88 policies adopted from 1870 to 1965, Walker^[2] created an innovation index, ranking

the states according to their propensity to be early adopters across a range of policies. He found that early-adopting states tended to be larger, wealthier, and more urbanized. These findings were soon challenged by Virginia Gray,^[3] who argued that patterns of policy innovation varied across different types of policies. The speed of diffusion and the trajectory of adoptions differed among the three policy areas she examined—civil rights, education, and welfare policy. Gray's work served to direct subsequent research toward the characteristics of *policies* and their interaction with state characteristics.

Later research supported some of Walker's contentions regarding innovative states. Robert L. Savage^[4] updated Walker's innovation scores, comparing 181 policies. He discovered that some states did tend to innovate across policy areas, but that changes occurred in the relative positions of states in the latter twentieth century, with only about one-half of the states retaining their former rankings. Survey research and interviews confirmed that states do in fact consider some states to be policy leaders.^[5–7] Grupp and Richards^[6] examined numerous policy areas and found that there was often consensus on leading states, but that these could differ by issue area.

Policy Determinants

Later studies tended to focus on the factors that influence adoption of a single policy. This policy determinants approach involves the examination of variables that Mooney and Lee^[8] described as resources, demands, and constraints. These factors can be categorized as external factors and internal characteristics.^[9–11] External factors might be the influence of federal grants, policy networks, and neighboring states. Internal state characteristics often included in these studies are social and demographic variables (population size, income, poverty rates, urbanization, education level, religion), political variables (public opinion, party competition, political culture, interest group activity), and measures of state resources (legislative professionalization, state budgets, or state wealth). The methodology for studying policy diffusion has become more sophisticated in recent years. Event history analysis, first used in diffusion research by Berry and Berry in 1990,^[9] has become the method of choice. This has

allowed researchers to explore the influence of factors that change in any given year: for example, regardless of whether there was an election that year, whether a neighboring state had passed similar legislation in the prior year, and so forth.

One limitation of these detailed studies is generalizing beyond the specific policy involved (see Refs.^[12,13] for a similar, more general critique of diffusion studies). A common approach to theory building has been to distinguish patterns within policy types. Hwang and Gray^[14] categorized state policies as either redistributive or developmental and conclude that political factors are more important in the adoption of redistributive policy, whereas economic factors are more important for developmental policy. Research on morality policies, which involve the legitimation of values or first principles,^[15,16] reveal distinct patterns that share little with either redistributive or developmental policies. Factors important in the diffusion of morality policies are demographic characteristics, such as the religious composition of the state population and political variables, such as interest group activity, partisanship, and public opinion.^[15] Administrative reforms such as e-government may depend more on factors such as legislative professionalization and professional networks. Because administrative reforms often lack political visibility, political variables such as public opinion, party competition, and interest group activity may not be relevant.^[17] Although some diffusion research draws comparisons across policy areas,^[18] no general theory of policy diffusion exists.

Policy Variation—Reinvention, Learning, and Policy Labels

Studies of innovativeness and the determinants of diffusion have described innovation as early adoption rather than the development or adaptation of an idea. Timing of adoption fails to capture important dimensions of innovation. Later adopters may engage in significant fine-tuning or may adopt more extensive policies, exhibiting arguably more innovative behavior than early adopters who merely copy a policy.^[19,20] Some evidence suggests that later adopters do tend to embrace more comprehensive or more permissive policies.^[8,19] Clark^[21] found that both “leaders” and “laggards” tended to have more extensive programs than middle adopters, except in the case of complex policies or redistributive policies, where laggards did not have broad programs. Hays^[19] also discovered that the tendency toward more comprehensive policies did not hold for those that were controversial and argued that ideology trumped learning in these cases.

Reinvention and comprehensiveness are often used as a means of measuring the amount of policy learning

that occurs through diffusion.^[8,19] As later adopters observe the actions of other states, they are able to elaborate upon them, especially because such policies are seen as less risky than in the earlier stages of diffusion. This represents a more sophisticated view of diffusion and begins to chip away at the normatively significant question of policy learning. However, other research is needed as well, to understand whether social learning occurs. We do not know, for example, whether adopters have observed the experience of other states and have drawn policy-relevant conclusions from these in fashioning their own programs. Programs may become more comprehensive in a sort of bandwagon effect, even if evidence emerges that a policy is not really effective. The rapid diffusion of tax incentives and competition among states to increase their packages of incentives defied the research of the time that such programs were not effective.^[22]

There is often wide variation in state policies that has little to do with increasing scope over time (see also Ref.^[1]). In her five-state comparative study of the adoption of the enterprise zone program, Mossberger^[22] found that the idea had diffused as a policy label, or a vague category of policies for distressed areas, encompassing wide variation. These policies had little in common other than the general idea of targeted incentives and the symbolic content the policy conveyed. Still, even within this context, “informed decision making” was possible, as states were well aware of what others had done and used this information to design programs to fit their own needs.^[22]

Sources of Diffusion—Regional Emulation, Networks, and Entrepreneurs

Walker's^[2] research traced geographic patterns of diffusion, revealing what he called regional systems of competition and emulation. This tendency toward regional emulation has been confirmed in numerous subsequent studies (among the more recent ones are Berry and Berry,^[9] Berry and Berry,^[23] Mintrom and Vergari,^[11] Mintrom,^[24] Mooney and Lee,^[8] Hays and Glick^[10]). Walker^[2] hypothesized that policy makers took cues from the most innovative states, their neighbors, and national state and professional organizations.

Walker's proposition that state and professional organizations provided a national diffusion network has been corroborated by later studies.^[22,25–28] Policy networks are often more extensive than these state and professional organizations because they may involve interest groups or issue advocates participating in national networks with contacts in the states.^[11,24,29] Mintrom's^[24] study of school choice examined the special role of policy entrepreneurs within such national networks.

Federal regulations, grants, and dissemination of information often stimulate the diffusion of policies across the states. Eyestone^[30] characterized this as “point-source” diffusion, emanating from the federal government to the individual states. Gray^[3] and Welch and Thompson^[31] noted more rapid diffusion of federally supported innovations. More recently, the networks in intergovernmental programs have been described as “polydiffusion” rather than point-source diffusion.^[22,28] Interviews with state officials and research in two different policy areas indicated that federal promotion of a policy idea is accompanied by the diffusion of information by state and professional organizations, and also interstate contacts. States report multiple sources of information in an interactive network.

There are some examples of policies that diffuse from the states to the federal government, in what is often called vertical or state-federal diffusion, but there has been less research in this area than in interstate diffusion. The examples of state experimentation with New Deal policies such as unemployment insurance and welfare policies are well known.^[32,33] Studies of more recent federal legislation document the influence of state programs on the Clean Air Act of 1990,^[34] welfare reform and other social policies,^[35] and the Empowerment Zones.^[36] Although it does occur, learning from state programs is often complicated by differences between federal and state policy needs, and the ambiguity of state experience.^[35,36]

Information Use

As the preceding review of the American literature shows, relatively little attention has been devoted to information use in the diffusion process—what information circulates in networks, how information is used, and how decisions are made. Two types of studies directly relate to what Rogers has called the innovation decision, or the use of information in diffusion. Comparative case studies of agenda setting have used comparative case studies to find out how and why issues arrive on the agenda in some states, but not others.^[27,37,38] Mossberger's^[22] study of the enterprise zones compared decision-making processes in five states. Two of the states fit the model of “bounded rationality” employed by Walker in his arguments, and by Richard Rose (Ref.^[39], see below). Three other states more closely resembled the policy streams model^[40] or the garbage-can model of decision making.^[41]

CROSS-NATIONAL DIFFUSION AND POLICY TRANSFER

Research on cross-national diffusion addresses geographic and temporal patterns of diffusion, the

determinants of innovation, and causes and sources of diffusion. In addition, however, literature on information use (cross-national policy transfer or lesson drawing) has flourished. Importing a policy across national borders is often more problematic than borrowing from a neighbor in the same country. Differences in institutions, political culture, resources, policy history, and other factors call for more attention to the way in which emulation occurs.

Timing of Adoption and Determinants

Early cross-national diffusion research also concentrated on searching for general models to describe and predict patterns of diffusion, much like the American concern with innovativeness as a trait or the policy determinants research. Collier and Messick^[42] examined the timing of adoption of social security policy. They found that the social security policies did not begin in the most economically advanced countries, but among nations with a medium level of development. A certain threshold of development appeared to be necessary to support such policy. It later traveled “up” the hierarchy of economically developed nations, and then switched to a pattern of spatial diffusion among neighboring countries. The Collier and Messick^[42] study suggested that multiple forces contribute to innovation—resources, political demands and constraints, and emulation.

Causes of Diffusion

Both “push” and “pull” factors are apparent in cross-national processes of diffusion.^[43] Voluntary adoption, based on the attractiveness of policies addressed to similar problems, is the most-studied method of policy diffusion. However, policies also spread through imposition or force. Colonialism and military occupation are the most draconian methods of policy transmission. Other “push” factors include supranational organizations and international treaties that promote policy diffusion through regulation and penalties, as well as through information exchange.^[44] Economically and politically powerful countries are also able to export their policies to other countries.^[43,45] Other factors facilitating emulation are geographic or ideological proximity,^[45,46] informal policy communities based on professional ties or expertise,^[46–48] or policy entrepreneurs.^[44,49]

Information Use as Lesson Drawing

Richard Rose^[39,46] offers a model of voluntary policy transfer as bounded rationality that he refers to as lesson drawing. Policy adopters may emulate the example

of others in whole or in part. For Rose, the impetus for cross-national policy transfer is a gap between policy performance and expectations. This performance gap stimulates a search for possible solutions. Lesson drawing uses the experience of others to bound the search for possible solutions, and to reduce the uncertainty and risk involved in a completely untested policy. Policy makers engage in a process of prospective policy evaluation, in which they estimate whether and how a policy that currently works in another country will work under the conditions of their own country in the near future. For lesson drawing, adopters do not need to have a comprehensive knowledge of the original policy and comparative conditions in both countries. Instead, they must only develop a sketchy conceptual blueprint of what will be required for success, given a comparison between the two policy settings and knowledge of key elements of the policy.^[46]

Diffusion as Policy Transfer

This model of lesson drawing is prescriptive and empirically based. Voluntary policy transfer, however, does not always resemble the model of lesson drawing. As Bennett^[50] showed, learning and emulation are not always the goals of those who use policy evidence from abroad. Foreign experience may be introduced merely to persuade policy makers to put an idea on the agenda. A program may also be adopted without examining how well the idea worked and what adaptations are needed. Dolowitz and Marsh^[44] argued that policy failure occurs because transfer is uninformed, inappropriate, or incomplete. Ideas can also be imported as a quick fix, a crisis response, or a strategy to quell political discontent.^[43,50,51]

Some scholars have suggested that cross-national policy transfer may resemble the opportunistic decision making of the policy streams or garbage-can models.^[49,52] Wolman^[49] used the term “policy transfer” rather than learning or lesson drawing precisely because he tested the rationality of the process, using the example of British emulation of the American Urban Development Action Grant. The British were unaware of the failures of the American policy, and were more concerned with adopting a general idea rather than a specific policy design. Robertson and Waltman^[52] saw the policy streams model as a general phenomenon in policy borrowing, because of uncertainty about policy outcomes and the potential for political conflict. Mossberger and Wolman^[53] surveyed 17 cases of cross-national policy transfer, finding that problems were common for these and other reasons. However, they also discovered some ways in which policy makers coped with the challenges of cross-national transfer. They recommended the use of “mixed

scanning” and various heuristics with the goal of achieving bounded, rather than comprehensive, rationality.

CONCLUSION

The study of policy diffusion has both limitations and promise. Research is often fragmented, with little generalizability across policy areas. Understanding of information use has come under greater scrutiny only since the 1990s, first on the cross-national level, and to a lesser extent, within the United States. Process-oriented studies of information use suffer from their own limitations, as they are often based on a single case, or perhaps a handful of cases. Since the beginning of the 1990s, more sophisticated methods have been incorporated into quantitative studies, allowing for a wider range of factors to be included in models. Network research has begun to examine the *influence* of networks and policy entrepreneurs, rather than just tracing the participants in networks. More studies address issues such as reinvention, learning, or rationality, and more still needs to be understood about whether and how diffusion improves public policy. It is only in this way that we will get closer to comprehending policy diffusion as social change.

Policy Implementation

Ann O'M. Bowman

*Department of Government and International Studies, University of South Carolina,
Columbia, South Carolina, U.S.A.*

INTRODUCTION

Implementation occurs in the middle of the policy process. It results from the stages that precede it, policy formulation and adoption, and it affects the subsequent stages: evaluation and redesign. The verb *to implement* means in its most basic sense, to carry out, to fulfill, or to accomplish. When applied to public policy, implementation is the process of putting into effect or carrying out an authoritative decision of government. This decision is most often enacted by a legislative body (e.g., the Congress, a state legislature, a city council), but it also can be a directive of the executive branch (e.g., a President's Executive Order, an agency's regulation) or a ruling by the judiciary. Implementation puts the objectives of policy adopters into action in an effort to accomplish desired results.

Implementation makes a policy happen, it gives a policy life. Policy formulation and adoption are necessary precursors, but implementation adds sufficiency. That may seem easy enough but several decades of research on policy implementation have demonstrated the complexity of putting policies into action. Few policies are self-implementing, most require concerted, coordinated action by actors other than those who adopted the policy. Implementation may stall, it may be diverted or subverted by implementors with conflicting interests, it may attenuate due to insufficient resources, it may encounter any number of pitfalls. A flawed implementation process makes the accomplishment of policy objectives all the more difficult. Since the early 1970s, researchers have sought answers to a fundamental question: What makes implementation successful?

DISCUSSION

"Policy implementation is what develops between the establishment of an apparent intention on the part of government to do something, or to stop doing something, and the ultimate impact in the world of action."^[1] In the simplest cases, implementation is handled by a single agency at the governmental level where the policy was adopted. When implementation is multiagency, and when it is intergovernmental, the

potential for slippage increases. Because the U.S. federal system is decentralized in design and, by the late 20th century, devolutionary in preference, most significant domestic policies are intergovernmental. Take, for example, environmental protection policies. Federal legislation such as the Clean Water Act requires the U.S. Environmental Protection Agency (EPA) to take certain actions but the bulk of the Act's implementation is the responsibility of state agencies. The Clean Water Act may have been enacted by the U.S. Congress and it may instruct the EPA to promulgate requisite rules, but it is Alabama's Department of Environmental Management and Vermont's Agency of Natural Resources, working with regional EPA offices, which are implementing the law. As it is in so many policy areas, implementation is increasingly a multiagency and multilevel process.

First-Generation Studies

Intergovernmental policy implementation is a complex process, a fact that emerged from a study of the "new towns in-town" program of the Johnson administration.^[2] This was confirmed in 1973 with the publication of Jeffrey Pressman and Aaron Wildavsky's book, *Implementation*.^[3] The subtitle said it all: *How Great Expectations in Washington Are Dashed in Oakland; Or, Why It's Amazing that Federal Programs Work at All*. Why did a well-intentioned, innovative employment policy enacted by Congress encounter so many obstacles during its implementation in the city of Oakland, California? The program provided funds for public works projects and business loans that would in turn produce jobs for unemployed minorities in Oakland. The level of enthusiasm for the program was high, agreement on the policy goals was substantial. But the program did not deliver on its promise. After three years, more than \$1 million in business loans were made, but few jobs were created and major public works projects had not commenced. The Oakland EDA case reinforced the new towns finding: intergovernmental implementation is not easy. In Oakland, it was the "technical details," but most especially, the complexity of joint action required in the implementation process, that doomed the program.

At more than 30 decision points, multiple participants with diverse, often conflictual, perspectives collided.

Research in the Pressman and Wildavsky mold analyzed how a single authoritative decision was carried out—or, as more frequently, not carried out. One valuable result of these case studies was the recognition of the complex nature of implementation. But, although these accounts provided contextually rich, detailed information about a specific program, it was difficult to generalize from them. Implementation succeeded (or was delayed, or was subverted) for a host of seemingly idiosyncratic reasons.

Second-Generation Research

Even as these so-called “first-generation” studies continued, another type of implementation research was underway. This work sought to develop analytical frameworks that identified factors important to implementation. In other words, this “second-generation” research focused on the determinants of implementation success, defined primarily as the achievement of policy objectives. Conceptual models of the implementation process were developed and tested in several different substantive areas. Two approaches predominated: top-down and bottom-up.

Top-down approach

Top-down models of implementation focus on the authoritative decision (e.g., the new statute) and the formal actors (decision makers) in an almost hierarchical fashion. The questions flowing from this model include: What did the law specify? What decisions were made? Did compliance (with the directives of the statute) occur? Were policy goals met?

Top-down researchers found that successful implementation was more likely if the following conditions existed:

1. Clear and consistent policy objectives embodied in the statute (or other legal directive).
2. A sound theory underpinning the statute, one that specifies the factors affecting policy objectives and gives implementors sufficient authority.
3. The placement of the implementation function in a sympathetic agency with adequate structure, supportive decision rules, sufficient funding, and adequate access to supporters.
4. Implementors with substantial managerial and political skill, and commitment to statutory goals.
5. Active support from organized constituency groups and key elected officials throughout the

implementation process, with the courts being neutral or supportive.

6. An absence of conflicting public policies and socioeconomic conditions that would weaken causal theory or political support.^[4]

Other things being equal, a policy that possesses these conditions is more likely to experience successful implementation than a policy lacking in them. Although seldom are all six conditions met, even in suboptimal situations, several steps can be taken to enhance the likelihood of successful implementation. There is no “routine” or “natural” path to implementation, four implementation scenarios are plausible.^[4] With the effective implementation scenario, as the label implies, implementation is smooth and swift. This is likely to occur in programs that seek only moderate changes in the status quo. In the gradual erosion scenario, implementation begins in a promising manner but slows precipitously as forces opposing the policy gain strength. The presence of numerous veto points wears down supporters and emboldens opponents. The link between the authorizing statute and the implementation process attenuates. The cumulative implementation scenario posits steady, slow progress toward implementation. Adjustments are made throughout the implementation process such that compliance from target groups is secured. In the rejuvenation scenario, initial start-up slows but then later resumes. Implementation is saved from the gradual erosion fate by changes in the statute (e.g., legislative clarification), in contextual factors (e.g., economic growth), and in agency characteristics (e.g., new leadership) that promote renewal of the implementation effort.

Bottom-up approach

Bottom-up approaches see implementation through a different set of theoretical and analytical lenses. Starting from the opposite end, bottom-up models focus on the existence of a public problem and the actors connected to it. To understand implementation, bottom-uppers look to the target population and the implementing environment.^[5] Street-level bureaucrats are queried as to their goals for the program or service and relevant strategies, activities, and contacts. This information provides the basis for the next step: constructing a broader network that is multilocal and multilevel. In effect, implementation is mapped from the bottom-up. Rather than unfolding from the top, implementation builds from the bottom or “micro-level.” To achieve successful implementation, local actors adapt policies and programs to fit local conditions. This helps explain how the same policy can produce very different implementation results from one setting to another. Implementation is determined

by the bargaining (explicit or implicit) in the policy subsystem: members of an implementing organization and their clients. Alliances are formed, coalitions are created, and the implementation process is managed. When a new policy or program fits the local context, implementation proceeds. When it does not, implementors seek to delay it or to otherwise thwart the objectives of enactors.

Assessing the two approaches

Top-down approaches are criticized for overemphasizing the role of central decision makers while bottom-up models are said to overstate the amount of autonomy that local level implementers possess.^[6] Regardless, second-generation research yielded several important findings about the implementation process. Chief among them was the recognition that implementation varies over time, across policies, and from one setting to another. Furthermore, it matters at what point in history implementation takes place and over what period of time.

Third-Generation Research

Third-generation research synthesizes the best features of both top-down and bottom-up approaches, in an effort to determine which variables, and in what setting, affect implementation. For example, policy-makers are encouraged to engage in both “forward mapping” and “backward mapping.”^[7] In forward mapping, policy objectives, implementation guidelines, and evaluative criteria are stated clearly and explicitly. But backward mapping shifts the focus to the local level and to target groups. The question becomes: “What has to happen at the local level for this policy to be successful?” Once answered, the follow-up question is: “What has to happen at the next level for this policy to be successful?” This procedure is repeated all the way back to the point of enactment. By engaging in this hybrid top-down/bottom-up exercise, policy-makers have a clearer understanding of the implementation process and therefore will select a better set of policy instruments. The result, the logic goes, is a policy that achieves its objectives.

Another way to conceive of implementation is as a multilevel subsystem full of messages, messengers, channels, and targets.^[8] Implementation is a dynamic process as messages are designed, sent, received, interpreted, and responded to. The content and form of the policy messages, and the standing of federal-level communicators among the implementers, act to induce or constrain implementation. At the subnational level, inducements and constraints are generated by organized interests, elected and appointed

government officials, and the focal state agency. These implementation-related interactions occur in a state setting that is structured by economic capacity, political conditions, and a set of situational variables such as the salience of the problem to a state, the amount of media attention given the problem, and a state’s organizational capacity.

States decide how they will implement a federal directive. Four patterns or styles are possible. The first implementation style, compliance, reflects a state context in which the new federal policy (and /or program) fits, i.e., the goals of the policy are in sync with state goals, the funding is sufficient, and implementors have the required skills. Moreover, it may demonstrate the value of incentives built into the policy that encourage rapid, unmodified implementation. In the second implementation style, strategic delay, a state delays implementation in an effort to make the new policy conform to the state context. This assumes that the new policy contains ample flexibility and discretion for these adjustments to be made. The state’s delay is strategic, thus it anticipates several rounds of negotiation and bargaining between federal-level actors and the state-level implementors. The third and fourth styles of implementation reflect a new policy at odds with a state context. In these instances, a state may simply drag its feet (the “delay” style) awaiting a judicial ruling, a change in the law, or a greater incentive to comply. Contrarily, a “defiance” state may opt to chart its own path, ignoring the dictates of the new policy. State policymakers may consider defiance preferable to the federal policy, but it may lead to the withdrawal of federal funding or the intrusion of federal enforcement officials.

Just as implementation is about communication, it is also about cooperation. However, implementation is often a matter of achieving cooperation among actors who are not necessarily inclined to cooperate.^[9] These “reluctant partners” who may hold different values and may have conflicting interests have to be induced to cooperate. But, unlike the traditional top-down argument, it is not the national-level actors who hold all the cards. Instead, authority is diffuse and subnational actors possess resources that they can marshal strategically. Implementation regimes form to guide the interactions of the various participants as they jockey for position. These regimes are composed of rules, norms, and procedures that shape the way participants interact.

Another influence on implementation is the working relationship that evolves between federal and state personnel.^[10] Two key dimensions of the working relationship are trust and involvement. In instances where trust and involvement are high, personnel at different governmental levels work together and achieve synergies, thereby facilitating implementation.

Where one or both of the characteristics are low, the working relationships are suboptimal. To move these working relationships into the facilitating variety, implementors are encouraged to increase personal contact, use multiple communication channels, share information, promote interagency learning, and provide timely communication and feedback. To increase trust among the actors, open dialog is encouraged while back-door and end-run communication tactics are discouraged, ends rather than means are to be kept in sight, meaningful input by all participants is welcomed, and a re-centering of the relationship on shared visions, whether policy goals, problem dimensions, or available solutions, is to be sought.

The growing use of networks to deliver programs and services underscores the lessons of the third generation. Implementation is often indirect with programs managed through complex networks of non-governmental providers such as non-profit organizations.^[1] Backward and forward mapping, effective communication, cooperative efforts, and increased trust and involvement are essential if implementation is to be successful.

CONCLUSION

The first generation of research on policy implementation produced fairly discouraging conclusions. Seldom, it appeared, were new governmental policies implemented as expected. Second-generation research sought to improve the situation by identifying solutions. However, the work was limited by an either/or definition of the problem: either top-down or bottom-up. This meant that the recommendations themselves were limited. The more recent third-generation research synthesizes the top-down and bottom-up approaches to produce more plausible explanations for why some policies are implemented successfully and others are not. It is not simply a matter of crafting a perfect piece of legislation for adoption. Nor is it enough to create a workable organizational structure

or to rally a cadre of supporters to the cause. Instead, successful implementation involves converting the potential energy of diverse participants into concerted, positive action. Policymakers are instructed to engage in forward and backward mapping. Implementation managers are encouraged to improve communication and foster cooperation, and to increase the levels of trust and involvement among implementers. On balance, as the use of networks grows, perhaps the most likely implementation pattern is one of strategic delay.

Policy Networks

Jack W. Meek

*College of Business and Public Management, University of La Verne,
La Verne, California, U.S.A.*

INTRODUCTION

Policy networks describe formal and informal social relationships among interested parties that form agreements to achieve individual and common goals in public arenas. Policy networks are viewed differently by political scientists interested in policy formation, by public administration scholars interested in policy implementation, and by sociologists interested in influence relationships among network partners. The influences of policy networks, and their great variety, provide evidence of social interaction that influence social behavior and influence public value. Some view these forms of associations as working alongside or even replacing formal government service and forming what has come to be described as governance. From another perspective, some forms of policy networks can be considered “dark” and there is a necessity to understand how these operate in addition to those policy networks that show promise.

POLICY FORMATION

Policy choices are expressions of social value traditionally thought to be developed by legislators who are representing the citizenry. In traditional theory, these choices are thought to be implemented by neutral public servants working in government bureaucracies. Political scientists have long observed that policy choices and governmental bureaucratic implementation are influenced by policy networks that are formed around the relationships and by participants closely involved in the policy choice. Those who decide (legislature), those who implement (bureaucracy), and those most affected (individuals, neighborhoods, industry or service) by policy form partnerships of interest that influence both the content and implementation of policy. These partnerships, referred to variously as subgovernments,^[1] as iron triangles or as cozy triangles are characterized by the cultivation of continuing relationships that engage in mutual exchanges that favor the needs of clientele groups agencies and representatives. Hugh Hecl^[2] broadened the frame of reference of these narrowly defined triangles to include a web of policy participants, with a variety of interests, that is

characterized as an “issue network.” Self-interest and exchange held issue networks together, but this form of policy influence was considered broader than the subgovernment form of relationship.

One meaning of policy networks is that policy formation is subverted or at least influenced by the central participants of the issue and that citizenry are kept far from playing any form of influential role in the process. Indeed, of concern about policy networks are the mutual benefits generated from political-administrative connections. No longer is there a neutral bureaucracy implementing public policy; it is now understood that bureaucrats are policy advocates. Networks replaced neutrality with self-serving outcomes of elected officials, selected clientele, and bureaucracy. On the other hand, policy networks can also be viewed as functional necessities of the modern nation-state where relationships of the most central players usefully orchestrate public will in competition with other interests in the state.

POLICY ADMINISTRATION

Public administration scholars have observed that public programs are increasingly produced and managed through various collectives.^[3] As networks, these collectivities include both governmental and non-governmental partners. For Laurence O'Toole, these “networks are structures of interdependence involving multiple organizations or parts thereof, where one unit is not merely the formal subordinate of the other in some larger hierarchical arrangement.”^[4] These networks are policy networks that are characterized by a “relatively stable relations between (different) governmental and (semi-) private organizations in which processes of policy making take place.”^[5] Thus policy networks warrant much attention, not only from the policy or political demand or “input” side, but also from the policy “output” or implementation side. And there are different positions on how to view policy network outputs and their impact on public governance.

One position, as evidenced in the work of Hugh Miller, is that an emergent characteristic of policy network (implementation) is administrative discretion

that approaches “political activism” or even political professionalism by civil servants.^[6] Such an outcome challenges the assumptions made by “progressive” public administration built around the principles of hierarchical control, scientific management, and neutral competence. The charge is that mutually supportive relationships spillover into the output/implementation side of policy where public administrators, motivated by a sense of agency expansion and self-promotion, become political administrators. The key issue is that administrators are hidden from direct public accountability and manipulate service design and delivery based upon a variety of reasons. It may very well be that administrators have captured and manipulated service implementation, which could serve many interests.

Another position among public administration theorists is to view the formation of networks as valuable tools in the implementation of public policy where administrative leaders face resource scarce environments.^[7] The size and nature of policy implementation networks range widely from linkages between two or more organizations to a formal coalition of organizations formally designed to carry out a broad mission. Networks, viewed through this frame of reference, are forms of collaborations designed to effectively carry out policy directives. The privatization movement effectively constructs a web of networks managed by government engagement that oversees policy administration.

NETWORK MANAGEMENT

The unique feature of policy networks is that they can be considered a third form of social relationships, the other two relationships are categorized as hierarchy and market.^[8] Whereas hierarchy and markets are usefully examined through the lens of superior-subordinate and rational self-interest, respectively, networks are much more elusive to understand. Network behavior is best matched with work on indeterminate behavior: participants come and go at will, there is no determinate pattern of leadership, power or hierarchy or leadership. Networks emerge and dissipate.

For public administration, accountability becomes a deep concern in policy administration networks. One study on the local management of economic development found that networks of multiple actors do represent an important form of governance. However, the management of networks adds to the tasks of public management and implies that both the capacity and policy making realm of cities becomes more decentralized and complicated.^[9] Indeed, if governance means a pronounced reliance on exchange and a de-emphasis of the role and strength of government, then serious challenges to equity and accountability may undermine the ability and legitimacy of government to govern.

In addition, the concern for policy networks is how roles are conceived as well as their concomitant expectations of rights, responsibilities, obligations, and duties that guide behavior.^[10]

The absence of hierarchy, the accountability vacuum, and the lack of role identity within networks have pushed public administration scholars to seek useful frames of reference that would guide public managers in determining what constitutes management cornerstones of policy networks. Robert Agranoff and Michael McGuire begin with examining the skills of the administrator and differentiating those required in traditional hierarchical public administration management (POSCORB) and those required of network management.^[11] The class of behaviors they found relevant in networks includes the following: activation, framing, mobilizing, and synthesizing. Activation refers to the identification and development of stakeholders that might be part of the network. Framing is the ability to establish rules of operation for the network. Mobilizing is the ability to coordinate and accomplish the goals and objectives of the network. Synthesizing refers to providing an environment when conditions are created to enhance network productivity. The combined effect of these skills is nearly “seamless in their applicability” and may result in outcomes that emerge and evolve rather than those that are targeted and achieved. Current research in management behaviors in networks is focusing on propositions based on a strategic-contingency logic, that program performance will vary based upon the problem context of the network.^[12,13] Drawing upon the examination of 12 network processes, Robert Agranoff has established 10 basic lessons in the management of networks (sharing burdens, sharing expertise, being creative, orchestrating agendas are examples), most of which reveal the fundamental need to be flexible within the fluid nature of network functioning.^[14] These may have been valuable skills in hierarchies, but it is in networks that these skills are preminent.

NETWORK PERFORMANCE

How well do these networks perform? Because policy networks involve many participants with multiple agendas, evaluating network performance becomes problematic, but necessary. One study^[15] examined publicly funded health, human service, and public welfare organizations from three levels (community, network, and organizational/participant) each of which has unique effectiveness criteria that often may be in conflict. The authors argue that while “service-delivery networks must be built and maintained at the organizational and network levels, overall network effectiveness will ultimately be judged by community-level stakeholders.”

To be successful, policy administration in networks calls upon different skills than those linked to successful administration in hierarchies. The very management of networks suggests the need for very different orientations and strategies of management.^[5] Reliance on collaboration from participants with different interests and who are accountable to different “publics” offers constraints in determining and achieving common goals. Based on a “theory of network management,” Meier and O’Toole found that managers who incorporated a networking management style (those who have greater interaction with environmental actors who are not direct line subordinates or superiors) had a significant impact on program performance and were able to influence program results.^[16] While this is perhaps a limited measure of managerial networking, it is a beginning in the establishment of what is effective in managing policy network.

GOVERNANCE

With the growth and evolving complexity of urban areas, policy networks have appeared and approach policy problems and solutions side by side with governmental bureaucracies. These networks are forms of governance. These networks are seen to be more responsive to the citizenry, in terms of participation and accountability, than the traditional governmental structures although these networks often include governmental structures. In fact, there is evidence that networks are forms of governance that have very enlightening features.^[17] Such features are more responsive to social problems that go beyond institutional boundaries set up by specific geographic jurisdictions that are represented by elected officials from that region. Administrative conjunction, the horizontal association of various networked public actors and the resultant administrative behavior of the network,^[18] best describes the administrative city-state in urban arenas today. Region-like collaboratives, such as councils of governments, regional transportation, and air quality boards, represent emergent forms of governance that engage in a web of system interaction that, as a whole, act as an urban regime of linked participants of mutual and competing interests. Indeed, R.A. Rhodes may be quite accurate when he states that these networks are “inter-organizational linkages (that) are the defining characteristic of service delivery.”^[19] How these networks are held accountable, and to whom, are powerful questions within this emerging dynamic of networked public administration. O’Toole reviews the role of bureaucracy and the emergence of networks in relation to the central democratic political norms of responsibility, responsiveness, and enhancement of political deliberation,

civility, and trust. He finds that networked public administration possesses many challenges, yet the lessons of such a status provide “both complications and opportunities to facilitate parts of the democratic ideal.”^[20] According to Erik-Hans Klijn and Joop F.M. Koppenjan, a central role should be played by government in the management of policy networks. It is their argument, that the government’s special resources and unique position can be used to represent the common interests of the public. This vital position means that government needs to play significant roles as network managers that arrange and facilitate interactive processes within communities.^[21] The authors defend this network approach to governance based upon the various theoretical foundations of the network approach and the emerging ability of that approach to explain program success and failure based on network determinants, including power, network management, and network structure. It would seem that much of the judgment about the impact of networks, as to how they influence the implementation of public policy, will rest on the nature of each network and how each network is managed.

CONCLUSION

Because policy networks are viewed differently by various authors and disciplines, it will be difficult in the near term to develop a coherent theory of networks. However, the work of Laurence O’Toole provides valuable parameters from which we can begin to address the development of network theory.^[4] O’Toole recommends that we explore the causal, conceptual, and descriptive dimensions of networks in order to improve our understanding of their role in public administration in a democratic society. LaPorte^[22] also offers three approaches to examining and understanding networks: 1) from within the network (the net rider) or those organizational units that traditionally function within the network system; 2) from above (the net thrower) or those who have a view of the entire network, such as a policy maker; and 3) from the side (the net puller) or entities that view a network not as an integral network participant but one that has cross-cutting interests or influence, such as a professional association or those interested in some form of reform. Each of these perspectives allows for different insights, different research traditions, and addresses different interests of the same network phenomenon. There have also been several advances toward a typology of networks framed mostly from the context of a local government perspective.^[7,9,15] Still others have felt that network theory for public administration and public policy is not likely to be advance on its own without considering networks as expressions of collective

action.^[23] Thus we have several valuable options from which to view policy networks. And, while most of the research on policy networks is focused on how networks and collaboration are quite positive, it is useful to note that networks can also have a dark side.^[24] Here the work of Jorg Raab and H. Brinton Milward is instructive: there are “dark networks” such as drug cartels, terrorist networks, arms smuggling that require response. Surprisingly or not, these dark networks share the same characteristics as “positive” or legal networks. The exception is that these networks rely on secrecy and the use of physical force. The key contribution of this finding is that network analysis is useful not only in examining positive networks, but “dark” networks as well. As we examine further the wonderful dimensions of policy networks as forms of governance, we can expect many different research strategies to inform us about how these entities are formed, how they behave, and what impact they will have on our lives.

Policy Sciences Approach

Peter deLeon

Christine R. Martell

Graduate School of Public Affairs, University of Colorado at Denver and Health Sciences Center, Denver, Colorado, U.S.A.

INTRODUCTION

This article describes the policy sciences, which have a unique approach to problem solving. The first part develops the evolution of the underlying assumptions of the policy sciences, while the second sets out an analytic framework derived from the policy sciences as a means of viewing policy decisions. Finally, a brief hypothetical example of how the policy sciences approach would be utilized in the “real world” is presented, based on a major highway and light rail construction project in Denver, Colorado.

THE EVOLUTION OF THE POLICY SCIENCES

The development of the policy sciences approach has generally been ascribed to the works of Harold D. Lasswell^[1–3] and his colleagues, soon after the end of the Second World War. The stated purpose of the policy sciences was to improve the quality of information offered to government and, by so doing, improve the quality of governance. But, the ontogeny of advice to the ruler goes back to virtually the beginning of recorded history, in which people wondered as to the application of knowledge to the public sector, to much the same end.^[4] Certainly the priests of antiquity were actively involved in political decisions, as kings would ask them to divine (and possibly sway) the “mood” of the gods prior to battle or even a royal nuptial. Later, of course, the princes of the church moved into political decision making with fewer concerns for the deities and more for their own secular livelihoods.^[5]

However, by the eighteenth century, the Age of the Enlightenment infused Western Civilization with the absolute certainty that, through study and reflection, a rational “truth” covering a wide range of subjects, including politics, could be discerned and acted upon. The history of the Progressive Era in the United States at least partially mirrors the purported marriage of good science and good government,^[6] even if politics and their administrations were somehow considered to be mutually exclusive.

The sociopolitical history of the twentieth century contributed in a sustained way to the movement of

higher education (i.e., universities) into the realm of social application. The First World War saw the emergence of psychology as a means to help winnow recruits for the American Expeditionary Force. The worldwide and sustained traumas of the Great Depression brought economics into virtually every government office. And, the horrors of World War II fascism made it apparent that governments could easily be used for ill purposes as well as good. This realization was especially clear for Lasswell, who spent the wartime years studying propaganda in the Library of Congress.

THE POLICY SCIENCES FRAMEWORK

Beginning in the late 1940s, Lasswell began to sketch out the thrust of the policy sciences, with three clear and abiding components that differentiated them almost radically from the traditional research canons as practiced in higher education; specifically, the policy sciences were meant to be:

- *Problem-oriented:* They were intended to address problems of significant social import rather than those of strictly academic concern; the policy sciences would not address the number of angels dancing on the head of any given pin, but, rather, the causes and alleviations of social unrest and inequalities. In Lasswell’s words (Ref.^[2], p. 14), “The Policy [Sciences] approach does not imply that energy is to be dissipated on a miscellany of merely topical issues, but rather that fundamental and often neglected problems, which arise in the adjustment of man in society are to be dealt with.”
- *Multidisciplinary oriented:* Lasswell^[2,3] saw the problems of the “real world” as having multiple “explanations,” such that in almost all cases, the application of a single discipline—be it law or psychology or sociology or economics—would be an unnatural constraint, be excessively narrow in scope, and therefore, in all likelihood, would fail to reveal the complete scope of the problem or its resolution. This tenet, of course, violated the entire departmental structure of the contemporary

university, which by this time was disciplinarily focused on narrow research topics.

- *Explicitly normative:* The effects of the Enlightenment were most apparent in the exposition of and general adherence to logical positivism, a “scientism” that neglected the role of norms and values and ethics in social decisions (Social Darwinism being one example). This was the situation in the social sciences, such as economics, psychology, and behavioralism in political science. Yet, Lasswell was certain that norms had an explicit place in policy making and needed to be emphasized in the policy sciences.

The third of these hallmarks was explicitly spelled out by Lasswell as he and Abraham Kaplan (Ref.^[7], p. 15) articulated that the policy sciences were designed to provide “intelligence pertinent to the integration of values realized by and embodied by interpersonal relations [such as] human dignity and the realization of human capacities.” More specifically, the next year, Lasswell wrote that “the policy sciences of democracy [were] directed towards knowledge needed to improve the practice of democracy” (Ref.^[2], p. 15), thus enshrining the normative concept of the “policy sciences of democracy.”

Two additional features of the policy sciences were their emphases on contextuality and the policy process. The first referred to the concept that no policy research could be conducted without a thorough understanding of the inherent contextuality of the problem; in other words, what were the conditions leading to the recognition of the problem, and in what environment did the problem exist? While this concept is certainly important in a world in which the policy sciences emphasize social problems, it lends itself to a fundamental, endemic concern of the policy sciences: if all knowledge is dependent upon the overall environment in which a problem exists, that naturally relegates a general *theory* of the policy sciences to a secondary position.

Lasswell also indicated a framework for understanding the events of (what he termed) the “policy process.” Formally posed in 1956, it has become the touchstone of most research in the policy process; many authors (e.g., Brewer and deLeon,^[8] Anderson,^[9] and Jones^[10]) have formulated their texts around the process, and numerous others have written on the various stages. As posed by Brewer and deLeon,^[8] the stages are as follows:

- *Initiation:* The recognition of a problem, an understanding of what goals (e.g., political, economic, and normative) are to be sought, and the preparation of possible options to attain these goals within their constraints.

- *Estimation:* The balanced assessment of the “costs” and “benefits” (broadly defined) characterizing the various policy options to be delivered to government policy makers.
- *Selection:* The stage at which decisions addressing the problem are made by the policy makers (generally, but not always and surely not exclusively) on the prior analytic work.
- *Implementation:* The stage in which the chosen option is put into practice, usually by administrators, but, more recently, through the non-profit sector, such that the programs have an effect on their intended recipients.
- *Evaluation:* The stage in which the program is assessed from a retrospective vantage point, its various aspects evaluated, and, when and where necessary, changes are made in the program and its implementation.
- *Termination:* In some cases, this is the final stage in the policy process, in which a program (for a number of reasons) is seen to have lost its effectiveness and is therefore terminated.

It is important to recognize that this framework (some have called it a “heuristic,”^[11]) is not presented as a formal “model” and does not assume any predictive capabilities. Instead, it is offered as a framework for understanding and structuring a particular problem for analysis, and, as such, serves a significant purpose.^[12] Moreover, its stages are clearly interactive with multiple feedback loops between them, rather than posing as a linear, lock-step progression.^[8]

AN APPLICATION OF THE POLICY SCIENCES APPROACH

Denver, Colorado, like so many American cities at the turn of this century, is experiencing severe transportation problems. Bisected by a major interstate (I-25), its citizens suffer, by their standards, long and crowded commutes, especially from south of the city, seemingly akin to frustrations found in Los Angeles, New York, and other major metropolises. At the same time, the development versus conservation (in Denver, known most cynically as “urban sprawl”) battle is in full tilt, with many political lances being broken over the resolution. In this fray, the newly elected Governor of the State offered what was to become known of T-REX (for TRansportation EXpansion), in which the Governor proposed a widening of I-25 south of Denver to eight to 10 lanes for approximately 19 miles, and a parallel construction and extension of Denver’s existing light-rail transit system, all at a promised cost of \$1.67 billion and a (projected) time frame of seven to

eight years.^[13,14] The State Assembly approved the entire T-REX package.

The “traditional” means of studying such a massive city works undertaking would have been little more than a textbook exercise in civil engineering (i.e., a mile of poured concrete times the number of lanes times the number of miles, with an unspecified “fudge factor,” in which time and costs were historically and heroically underestimated; witness Boston’s current “big dig” fiasco as evidence). Under contemporary standards, this process has been vastly complicated, as “new” conditions—such as endangered species, noise pollution, how it would be paid for (in this case, highway trust funds) and, of course, litigation and the delays entailed—have to be taken into account. From the perspective of the policy sciences, however, T-REX is naïve at best, and a disaster at worst.

The policy sciences pay close attention to the goals underlying a project *before* designing the project. For instance, if the goal were to reduce commuting time, then widening the interstate is only one option; others, such as developing multiple civic and commercial centers (especially with the possibilities of electronic communication) would also reduce commuting time and, probably, at a fraction of the cost. In the specific case of T-REX, the clear purpose is to expedite travel times along the I-25 corridor by expanding the freeway, but with little understanding of the long- and short-term consequences.

Assuming for the sake of the argument that the proposed T-REX plan works as advertised, its response might well be short-lived in its effectiveness. When more automobiles can be accommodated with the newly widened I-25, the housing and commercial real estate markets will again feature residential and business locations along the southeast corridor (now advertising a “speedy commute” enticement), thereby selling more property and dwellings, and thereby raising the number of residents and, concomitantly, the volume of vehicles using the corridor. In time, I-25 will become as crowded as is currently the case, and over a billion dollars will have been spent to little avail (excepting a short period of time before the real estate markets adjust). Likewise, more cars will be able to access downtown Denver’s commercial areas (even if the individual driver’s commute time is no faster), without much attention being paid to the ability of downtown to absorb the new visitors. For instance, will there be sufficient parking, or what if commercial builders opt for suburban expansion? If these were the only problems, T-REX might be understandable, but in order to build the new system, many homes and businesses will have to be literally razed, and those houses presently set back from the current I-25 route will become cheek-to-jowl to the noisy interstate. None of these are especially attractive futures.

In contrast, the policy sciences approach would have insisted on a wider variety of perspectives being examined before a contract was signed. In addition to civil engineering, these perspectives would have included, for example, urban planning, community building, sociology, political science, environmental management, and ethics.

An urban planning perspective would consider a variety of demographic shifts as well as a plan for directed growth of the city. While transportation planning (i.e., the nexus of planning and civil engineering) more narrowly focuses on moving people from point A to point B in the most expedient way, urban planners would also consider the growth consequences of highway expansion on the community and might investigate whether the areas within the expansion zone will be able to support services for the projected population increases. Moreover, urban planners actively involve the affected citizens in the planning process to determine such questions as: Will the area have a strong enough tax base, be able to accommodate new schoolchildren, be able to provide clean water, provide recreational facilities, process sewage, and collect refuse, in short, be a comfortable “home” to its businesses and residents?

In conjunction with this, a community building perspective would question whether the expansion of transportation would destroy existing communities and whether it would lead to building new and viable communities. Already, strong opposition by communities to be affected by the T-REX construction clearly signals that the project subverts the value of established community to that of future real estate growth and the concomitant perceived ills of urban sprawl.

The sociology perspective might consider the social forces to explain group behavior. What are the reasons explaining the need for expansion in such a direction? Is there a reason why people are choosing to live 10 miles outside the city when there is available housing within the city limits? Is there an urban problem that can be resolved to ameliorate the volume of suburban-to-urban commuters? A sociologist also might view the process through a series of lenses, such as gender, race, and economic class, lenses that T-REX has studiously avoided.

A political science perspective would consider the relative affect of interest groups, such as the “highway” lobby and the home owners’ association, to understand the resulting plan, specifically, the political pressure for and against transportation expansion. Political scientists would be especially concerned with the manner in which the decision was made, and who were the relevant participants. From a normative perspective, political science would ask why this particular route was chosen over alternative placements, as well as who is being displaced (or advantaged).

Supporters of environmental management might look at the expansion from the view of its affect on the environment. Would the highway be expanded into areas of fragile land? What repercussions would expansion have for urban sprawl and the use of soil and water? Would, for example, suburban development encourage the planting and maintaining of water-hungry green lawns in a desert climate (that is, its effect on urban water tables)? An environmentalist would consider the consequences that development policies have for natural resource management. In short, the environmentalist would argue strongly for the conservation side of the conservation/development coin, or what is broadly known as “sustainable development.”

An ethical perspective might question whether engaging in transportation expansion is in light of the alternatives and question why movement from point A to point B is so important when alternatives exist. Ethicists may suggest that transportation expansion is normatively problematic because of the potential negative repercussions for social mobility, environmental damage, and economic integration. Instead, they may propose solutions that are considered more justified, but in any case, alternatives will be proffered. For instance, ethicists might propose to develop a system of regional minicenters rather than a Denver-centric spoke-and-wheel metropolitan area, or they may abandon transportation expansion altogether in favor of a series of telecommute centers or education programs.

Considering these (and similar) approaches, it becomes apparent that the T-REX expansion deals with a great more than the technical engineering question of laying the road and a light-rail transit system. The policy sciences approach would more broadly recognize that the issue of traffic congestion entails many more issues than simply “moving bodies,” that is, there are many aspects to this, and most, problems. The perspectives above need not be mutually exclusive. For example, a sociologist’s view may complement the views of community builders or planners, and a planner may resonate with an environmental manager. Regardless of how well perspectives converge, viewing

the T-REX situation from different lenses illustrates how a policy problem is multifaceted, with each perspective introducing a host of issues. The more that the policy sciences approach introduces a series of related issues, the more policy goals become multidimensional, and the acceptable solutions necessarily become multidisciplinary.

Policy Termination

Mark R. Daniels

Department of Government and Public Affairs, Slippery Rock University of Pennsylvania, Slippery Rock, Pennsylvania, U.S.A.

INTRODUCTION

Policy termination has been defined by Garry Brewer and Peter deLeon as “the deliberate conclusion or cessation of specific government functions, programs, policies, or organizations.”^[1–3] Elaborating upon this definition, another termination researcher explains that “termination is premeditated behavior, with the intent of ending a particular public organization or policy.”^[4] Both of these definitions do not recognize changes in policy emphasis or jurisdiction, which may be organizational attempts to redirect activities and to justify existence, as policy termination. In addition, both of these definitions define policy termination in a broad sense, including both organizations and their programs and policies under the same golf-course-size umbrella of policy termination. This broad definition leads to confusion because some termination researchers, notably Herbert Kaufman, have studied organization termination as a phenomenon distinct from policy termination.^[5,6]

TERMINATION RESEARCH

Eugene Bardach edited the first collection of termination studies in a special issue of the journal *Policy Sciences* in 1976, and two additional collection of articles were published in journals in 1997 and 2001.^[7–9] Bardach argues that termination is actually a special case of policy adoption: The adoption of policy A requires the elimination or curtailment of policy B. The uniqueness of this form of policy adoption lies in the vested interests of those who oppose the termination of policy B. Bardach observes that when termination does occur, it does so with either a bang or a whimper. In the former case, resistance to the termination of policy B is so intense that when it finally does occur, it does so in an abrupt, forceful fashion. In the latter case, termination occurs as a result of a long-term decline in the organizational resources that supported policy B.

Books on Policy Termination

In 1997, two books, both providing a comprehensive treatment of policy termination, were published: *An*

Operational Approach to Policy Analysis: The Craft and Terminating Public Programs: An American Political Paradox.^[4,10] *An Operational Approach to Policy Analysis* attempts to operationalize the craft of policy analysis, and each chapter provides step-by-step instructions on different approaches to policy analysis and ends with a summary section that provides a check list for policy analysts. This format is very innovative and addresses the needs of policy analysts for a how-to book. Its format and style definitely fill a gap in the policy sciences literature. Chapter Five, entitled “Implementing Termination,” follows the general format of the book and provides step-by-step instructions based on published research. This chapter makes two very original contributions to understanding policy termination. First, the Defense Base Realignment and Closure Commission (BRAC) is given as an example that demonstrates the importance of agenda control. Second, they introduce, for the first time, the concept of ethics in the termination process. The idea that a policy analyst has an ethical obligation to citizens and to the political system, in general, introduces an additional dimension to the discussion of policy termination.

Terminating Public Programs attempts to respond to the three tasks that face policy termination researchers as identified by deLeon: 1) to compile cases on termination; 2) to acquire an understanding of the factors leading to termination and build theories; and 3) to develop strategies and tactics that lead to successful termination. The book offers seven conclusions about the implementation of policy termination (see [Table 1](#)).

First, termination rarely has economic justification. Termination usually costs more than policy continuation, at least in the short run. Termination is usually a result of political rather than analytical decision making. Political values and ideologies often pave the way for termination, instead of economies or efficiencies. There is general agreement among researchers that while cost-cutting rhetoric may be used as a tactic by terminators, in reality, no short-term savings result from termination.

Second, termination is highly political and hard to achieve. The American political system is characterized by multiple access points to government. Affected interest groups can gain access to government

Table 1 Seven conclusions about policy termination

-
1. Termination rarely has economic justification.
 2. Termination is highly political and hard to achieve.
 3. Termination requires co-optation of opponents.
 4. Termination often involves changing ideologies.
 5. Termination is followed by rebirth.
 6. Successful termination is difficult to predict.
 7. Termination is an American political paradox: Everyone supports it, everyone opposes it.
-

decision-making processes through legislative hearings, the enactment of legislative bills, the executive branch, the bureaucratic apparatus of government, the courts, and even through the media. These multiple points of access provide many opportunities for organized groups to oppose changes in specific government programs. Any attempt to terminate a government program, policy, or organization is potentially at the mercy of the entire political system. The reason termination is so difficult to achieve is because it is essentially political in nature. Termination is hard to accomplish within an incrementally oriented political system.

Third, termination requires co-optation of opponents. Termination is possible only through determined, prompt action by strong political administrators who are willing to engage, if necessary, in political co-optation of opponents. Political leaders of successful terminations have successfully blocked or cut off the political access points of opposition groups.

Fourth, termination often involves changing ideologies. Successful termination is often the result of a change in the application of certain principles, or assumptions, about what services are appropriate for government to sponsor or how these services should be delivered. Because ideologies can be neither proved nor disproved, the application of ideology to the continued existence of a program does not involve issues of performance, effectiveness, cost, or economies. Instead, termination in this case is conducted on the basis of a change in principle.

Fifth, termination is often followed by rebirth. Termination appears to be a journey more than a destination, and many programs come back to life after the terminators have left the political scene. Those programs claimed by death face neither heaven nor hell, but a potential after life. There is life after death, at least in the public sector.

Sixth, successful termination is difficult to predict. The timing of termination—that is, when an agency will actually die—is something of a mystery. The interaction of social and economic events over time may create changes in an organization's environment beyond which the organization can respond effectively.

If the organization cannot respond effectively and adequately to its changing environment, the organization becomes terminally ill and will soon die. This interaction over time is so subtle that it escapes the detection and measurement by researchers. Termination researchers do not predict terminations, but instead conduct autopsies: they study the demise of programs, policies and organizations after they have been terminated.

Seventh, termination is an American political paradox: everyone supports it, and everyone opposes it. The termination of programs, policies and organizations takes place within the constraints of democratic values such as citizen participation, political representation, and old-time pork barrel politics. American government is a pluralistic democracy in which multiple interest groups, representing different and conflicting public opinions, can take advantage of multiple access points into the political system. Opposition to terminating public programs, policies and organizations is not only expected but is a political right of those adversely affected.

A Termination Process Model

Susan E. Kirkpatrick, James P. Lester and Mark R. Peterson have made a significant contribution to the study of policy termination with an article that proposes a process model of termination based on their extensive review of literature.^[11] Fig. 1 presents their model, called “A Process Model for the Termination of Public Goods.”

Under the heading “Inherent Characteristics,” the *raison d'être*, or reason for being, refers to the perceived mission of the organization or policy and the legitimacy that the mission is given in the minds of the public and political leaders. According to the public involvement literature references in their article, any organization or policy that is not seen by the public as addressing some important public problem is living on borrowed time. Longevity has been identified as an important factor in the ability of an organization to survive and to avoid termination. Mature organizations are most immune to termination. Under the heading “The Political Environment,” the prevailing ideology refers to the importance of ideological support for a program that may shift with political changes in leadership. The size, strength, and determination is also an important political variable involved in termination. Another factor is the powerful allies that may assist either termination or antitermination efforts. The opportunity for compromise possibilities is another variable in preventing termination. Finally, speed is important for would-be terminators who need to act swiftly in order to keep one step ahead of

Fig. 1 A process model for the termination of public goods. (From Ref.^[11].)

termination opponents. Under the heading “Constraints,” the termination barriers of antitermination coalitions, dynamic conservatism, legal obstacles, and start-up costs are taken from the work of Peter deLeon. Antitermination coalitions are composed of constituents, both from the public and elected officials, who oppose the termination of a particular organization or policy. Dynamic conservatism refers to the ability of organizations and policies to adapt to changing environments and ensure their survival. Legal obstacles are efforts to block termination made through the legal process, for example, obtaining an injunction. Start-up costs refer to the cost of ending one program and losing the sunk costs already invested in the program. Finally, fear and uncertainty refer to the apprehension that administrators and political leaders have concerning the changes that may occur as a result of the termination of a program.

Their effort to develop this framework is an important contribution to the study of policy termination. Similar to all other discussions of policy termination, their analysis of policy termination is retrospective. While autopsies are useful in determining the cause of death, the topic of policy termination continues to lack a framework that is able to predict termination.

CONCLUSION

In his introductory article for the first symposium on policy termination, Eugene Bardach referred to policy

termination as an “underattended issue.” The so-called balancing of the federal budget and the elimination of the federal deficit during the late 1990s has turned popular political attention away from cutting government programs. For example, conspicuously absent from the 2000 presidential election were plans voiced by any of the candidates to eliminate agencies or programs, or reform government through termination of outmoded or inefficient policies. Nonetheless, as an academic topic, the factors surrounding termination are only beginning to be identified, and models of the termination process are beginning to emerge. What is lacking is a predictive equation that regresses the independent variables connected to termination and provides explanatory power with little error. While we are not yet at the point of making accurate predictions about the event of termination, recent research has brought us further down the path with new case analyses and models.

Policymaking in Local Government

Jeremy L. Hall

*Department of Government, University of Alabama at Birmingham,
Birmingham, Alabama, U.S.A.*

INTRODUCTION

The public policy-making process is shaped by formal and informal institutions, rational actors positioned by values, and issues derived from the decision-making context. Local policy making follows this model and, as such, is quite distinct from state and national policy making. This essay explores each of these constructs to shed light on the process and products of local policy-making efforts.

LOCAL GOVERNMENT STRUCTURES

Local jurisdictions derive their existence and authority from sovereign states and are, consequently, only able to exercise such discretion as their parent states grant by law. They are, in essence, corporate entities. At opposite ends of a spectrum of state-granted discretion to local governments are Dillon's rule and Home rule. Dillon's rule—the traditional restrictive view of local government—provides that local governments can exercise three kinds of power: 1) those expressly granted in words; 2) those necessarily or fairly implied in the powers granted; and 3) those powers that are essential to the government's declared purpose (indispensable, not merely convenient).^[1] The doctrine is named after Judge Dillon, who authored it as Chief Justice of the Iowa Supreme Court in 1868.^[2] While some states are very restrictive in their grants of power to localities, others follow a model of Home rule, granting local governments broad discretion to self-determine policy where not otherwise restricted by state or federal mandate. Home rule or Charter governments are governed by a charter that acts much like a constitution, establishing boundaries within which local governments can exercise policy discretion.

Home rule counties are granted much broader authority than their non-Home rule counterparts, though they are still constrained by statute. For example, Knox County, Tennessee, has a unified city/county government operating under a home rule charter. In 1994, a referendum was held by Knox County voters to impose term limits on county-elected officials. The term limit requirement was not observed, however, and a court challenge led to the January 2007 Tennessee Supreme Court decision, recognizing

the charter's validity and vacating a number of county offices held by re-elected individuals, covered by the term limit amendment to the charter.^[3]

Related to the Dillon's rule/Home rule dichotomy is the structure of local general-purpose governments. Counties or parishes collectively occupy all of the territory in each state and act as the traditional administrative arm of the state. Municipalities (towns and cities) provide urban services to more densely populated incorporated areas. Cities operate under one of three general structures: the mayor-council form (with either a strong or a weak mayor); a council-manager form; or a commission form. The nature of these structural differences articulates the available entry points for policy change. And local government structures may vary considerably within a given state; Kentucky, for example, includes cities with council-manager, commission, and mayor-council forms, and the power and duties of the mayors also vary considerably among cities with the latter form of government.^[4]

Mayor-council systems of the strong mayor variety (where the mayor exercises budget authority, controls the council agenda, and possesses a veto) represent one extreme. In this setting, the council is the deliberative legislative body that sets policy (subject to a mayoral veto), and the mayor is the executive responsible for implementing and managing policy. Local policies are often so narrow in scope that there is little discretion to delegate, and, as such, administrative policy making is limited at the local level. This is not meant to imply that street-level bureaucrats in local government do not exercise bureaucratic discretion—police officers, social workers, and others certainly do. At the opposing end of the spectrum, council-manager governments lack a bona fide executive. So, the legislative council sets policy and directs a city manager (who serves at the council's discretion) to carry out policy and oversee the administration. Although cities are discussed here, similar distinctions exist in county government. A legislative body of representatives (referred to as a fiscal court in some states) and a separately elected county executive (sometimes called a judge executive) corresponds to the mayor-council system in cities, and a county manager corresponds to the council-manager system in cities. Systems that employ administrative managers in lieu of an elected executive are considered professional or reformed.

An additional distinction of local government structure is the divided executive. Whereas city mayors typically oversee all administrative operations, county executives are divided. Growing out of the Jacksonian ideal of specialization in government, county governments typically include a judge or other executive who presides over the fiscal court, a county clerk, sheriff, coroner, and various additional offices, including property valuation administrator, surveyor, attorney, and so forth. The result is increased potential for divided political control of local government operations, but the degree of specialization within each position limits the policy-making authority of any one individual. Moreover, these elected officials are often little more than administrative managers, carrying out the administrative duties delegated them by the state (including tax collection, issuing licenses, recording vital records, and similar functions). In these divided executive systems, real policy leadership ability rests with the judge executive or county executive and the legislative body.

The third branch of government—the judiciary—is also unique at the local level. Judicial preferences are expressed at the local level through the electoral system. Unlike appointed federal judges, local judges are elected to office, although usually in non-partisan elections. Judges who best represent local residents' views are elected to office, and they are then able to exercise discretion within the bounds of state law.

SPECIAL DISTRICTS, JURISDICTIONAL OVERLAP AND POLICY FRAGMENTATION

In addition to general-purpose governments, local policy making is further fragmented by the presence of single-purpose special district governments or public authorities. Special districts were created in large numbers during the 20th century, and non-education-related special districts have been the fastest growing form of local government. Special districts serve multiple purposes, among which are the professionalization of government services, a movement to make services more business-like and self-sustaining through service fees, and, perhaps, most importantly, movement of debt for capital off general fund budgets of general-purpose governments. Moving debt off-budget enhances government credit ratings and avoids debt limit requirements.

Special districts are governed by boards of directors or councils either appointed by general-purpose governments (utility boards, for example) or elected to office (school boards, for example), giving them the ability to operate autonomously under a corporate model. They have their own budgets and often have their own revenue streams derived from service fees

or earmarked tax receipts. Such districts include schools, libraries, utilities, conservation, economic development, and so on, giving each distinct policy arena its own institutional presence. They share many characteristics with cities and counties and are integrally involved in numerous substantive policy areas.^[5] Consequently, actors in each policy field and citizens interested in participating in that substantive policy process face very specialized formal institutions. The specialization may add simplicity to governance, but irregular and overlapping jurisdictional boundaries in the policy environment also lead to significant confusion for citizens seeking public officials responsive to their concerns—they often find it a daunting task to locate the accountable person with proper authority to act on their particular concern.

Fragmentation within urbanized areas has become common, as the promulgation of special districts and incorporated municipalities has led to overlapping or complex service areas.^[6] Unique communities with unique tax structures and service offerings appeal differently to different individuals. Local policy discretion provides the opportunity for cities or communities within a metropolitan area to differentiate themselves, thereby providing the bundle of services most desired by their residents, and setting the stage for savvy residents to relocate to areas that maximize their utility.^[7] Fragmentation produces choice. However, the overlapping nature of the fragmented system also creates confusion, and the cost of relocation means that the real effects of government competition are realized with either new residents or movers within an area, making locational choices.^[8]

The special district movement contributes to the “hollowing out” of the administrative state, which refers to the movement of service provision out of government agencies more generally. Contracting out to private and non-profit organizations has become an important method of local service provision. For example, waste management is now commonly contracted to private firms, as is road maintenance, snow removal, and various other public services traditionally performed by local governments. Local governments act as a source of funds, with services performed by the lowest, or in some cases the most qualified, bidder.

As one considers governments of smaller size, problems and issues that were internalized at higher levels of government become external and are more likely to fall outside of any one local government's sphere of responsibility or influence. Thus, policy solutions at the local level are dependent on coordination through regionalism and interlocal agreements. To this end, states have created regional entities to coordinate local planning. Regional planning commissions, area development districts, and similar entities bring together elected officials from the region on their

governing boards. These entities then oversee regional planning efforts, facilitate coordination among peer governments in addressing regional problems (such as growth, transportation, environment, conservation, and economic development), and provide technical assistance to small local governments that lack capacity to solve their problems independently. For example, traffic problems and transportation require coordination and agreement between jurisdictions to prevent bottlenecks and congestion at jurisdictional boundaries. In the case of waste management, economies of scale can be gained by coordinating local efforts; specifically, one large regional landfill can be operated much more efficiently than several independently operated county dumps. In some instances, local governments have even coordinated economic development initiatives, such as regional industrial parks, that pool resources in attempts to capture scarce benefits. Economic development is a traditionally competitive policy field, in which local governments compete with one another to lure firms to their area.

AREAS OF LOCAL POLICY SALIENCE

Economic development is one of the predominant policy domains at the local level.^[9] From planning and zoning decisions, redevelopment and revitalization efforts, and industrial parks and other recruitment efforts to utility and transportation expansion and amenities development, most local government efforts focus on growth, expansion, and improvement of the community; the quality of life its residents experience; and the tax base on which government solvency depends. The importance of economic development to local communities is evident in the landmark 2005 *Kelo v. New London* decision by the U.S. Supreme Court; that decision qualified a locality's use of state-granted eminent domain to allow development by a private enterprise as a public interest.^[10]

Economic development policy epitomizes the policy process at the local level. It involves residents who mobilize to support or oppose development initiatives, corporations seeking locations and investment opportunities, and elected officials actively seeking credit and publicity for flashy public works projects in the public eye. Grassroots interest groups are able to form almost instantaneously to affect local policy. For example, such groups form for such diverse purposes as protesting destruction of historic structures, pushing for more favorable decisions from an unpopular family court judge, and opposing the construction of a new interstate highway advocated by local officials.

Although economic development has traditionally been a key beneficiary of local policy attention, local governments have recently become the new arbiters

of public health. Landmark regulatory efforts by cities across the United States have limited smoking in public places, especially restaurants, bars, and government buildings. In January 2007, Bangor, Maine, issued a ban on smoking in automobiles when children are present. New York City recently passed a contentious ban on the sale of foods containing trans-fat. In addition to these actions that regulate personal behavior, other efforts are more broadly conceived. For example, appeals courts in California have upheld local ordinances restricting big box stores such as Wal-Mart from locating in their communities. The city of Arcata, California, has taken perhaps the greatest liberty with local policy making, holding the distinction as the first city to prohibit local officials from complying with the provisions of the U.S. Patriot Act. The spread of policy innovations from one government to another has been shown to be the result of a combination of internal determinants and diffusion.^[11] In studying local policies, a combination of factors have been shown to affect policy development and diffusion, including local government characteristics, establishment of interest groups, presence of regional associations, and focusing events that heighten the salience of the policy.^[12] So, where local conditions are conducive, local officials look to policies adopted elsewhere for potential solutions. Smoking bans have diffused across metropolitan areas in such a fashion.

THE INSTRUMENTS OF LOCAL POLICYMAKING

As local governments are closest to the people, they typically deal with issues of localized concern.^[13] From limiting speed on city streets to implementing stringent building codes to identifying and restricting nuisances such as junky yards, loud music, and foul smells, local governments issue ordinances in response to the concerns people face in their day-to-day lives. The common form of local policy instrument is the ordinance, and, whereas many votes can be taken by voice, ordinance votes in most places require a call of the role of the local legislative body. Ordinance votes in most local governments require readings at three meetings, the third of which is for the official vote on the measure; this effectively prevents decisions from being made in haste and provides significant time for concerned local citizens and businesses to voice their concerns and provide their input regarding the matter in question. When controversial issues arise, local government bodies may also call hearings for the express purpose of gathering public input outside the context of meetings convened for conducting business. Most states provide for local government entities to conduct business according to open meetings and administrative

procedures laws that provide for all meetings to be announced in advance and that restrict the ability of the local decision-making body to conduct business behind closed doors.

Whereas ordinances are the official actions of local legislative bodies, some states provide for policy decisions to be made by the people directly. Referenda and initiatives place policy decisions in the hands of the people; in the case of the initiative, it is directly so, while referenda are initiated through local legislative bodies and then sent to the people for a vote. Initiatives and referenda are frequently used policy tools in some states, although use varies significantly from place to place. In some areas, such as California, for example, local initiatives are widely accepted mechanisms for expressing the public will, leaving policy decisions in the hands of the people rather than their elected officials. Such was the case with Proposition 13, in which California voters capped property tax rates. At the local level, with the passage of Proposition F in November 2006, San Francisco became the first city to require businesses to provide paid sick days to workers. Highlighting the importance of mobilized interests in local policy making, this measure was pushed by an advocacy coalition led by the Coalition for Paid Sick Days.

INFLUENCE OF LOCAL INTERESTS AND INTERGOVERNMENTAL RELATIONSHIPS ON LOCAL POLICY

In 2000, Kentucky passed Senate Bill 247, which liberalized the Commonwealth's alcoholic beverage law by allowing dry counties and cities (of any size) to hold local ballot referenda to approve the sale of alcoholic beverages in restaurants by the drink—a privilege previously reserved to larger territories. This exemplifies the central role of the state in determining the scope and authority of local policy making. The presence of referenda provides formal opportunities for policy participation, leading to group mobilization and more pronounced policy conflict surrounding direct policy decisions by local residents.

Local policy making is not distinct from the political process, but whereas political parties shape public opinion at the national level, at local levels, opinion positions the parties. States or localities with more liberal opinions result in more liberal political parties.^[14] So, at the local level, opinion tends to be fairly homogeneous and parties position themselves in relation to that opinion, often making the differences difficult to discern.

Just as states formulate policy independent of federal policy activity, so local governments formulate policy where states leave discretion to them.^[15] Local

governments are able to act autonomously within the bounds established by their states, and they are able to collaborate regionally to address special problems and policy issues. They are not immune, however, from the pressure of incentives and disincentives from higher-order governments. Fiscal federalism is the relationship of fund transfers among local, state, and federal governments. The availability of grant funding often leads local governments to pursue projects and make policy decisions that do not align perfectly with local preferences, because grant funds reduce the cost to the local government of the sponsored activity. That is, local governments assume the policy preferences of the higher-order grantor governments over the preferences of local residents. Over time, governments can become accustomed to the flow of intergovernmental revenues into their coffers and become dependent on that stream of funding. This has become more difficult over time, as the use of revenue sharing and block grants has been replaced with project grants that are less fungible with general revenues. However, local governments still face the choice of increasing services or amenities by accepting state or federal funds vs. using local funds to provide services that are in greater local demand. Matching requirements for federal funds often mean that localities have to devote a portion of their own-source revenues to fund projects, taking away from projects of local priority, and, to the extent revenues are not available, local governments may resort to debt financing to meet match requirements and sustain the flow of intergovernmental funds into their budgets.^[16]

CONCLUSION

All in all, policy making at the substate level is unique to the particular government in question, shaped by state law, the form of local government, local problems and issues, mobilized interests, the presence of special districts, and the incentives or disincentives placed on those governments through funding opportunities from state and federal programs. Extending grants of home rule authority, increased use of initiatives and referenda, and creation of new special districts likely mean that local policy making in the future will be characterized by greater local discretion and increasingly complex service delivery systems and with greater attention to governance, as interests mobilize to support policy innovation.

Policy-Oriented Social Science Research: Measuring the Benefits

Henry E. Kilpatrick

*Econpolicy, and School of Public Policy, George Mason University,
Arlington, Fairfax, Virginia, U.S.A.*

INTRODUCTION

The primary focus is on the assessment of research that eventually supports a particular policy program. Advocacy research, or research that is funded by an interested party and designed to bolster a particular position, will not be covered here.

Policy-oriented social science research is a *public good*. A public good has the following attributes: 1) it does not cost anything for another individual to enjoy its benefits, i.e., the marginal cost, or the cost of producing one additional unit of a public good, is zero and 2) it is difficult or impossible to exclude individuals from the enjoyment of a public good. The owners of social science research cannot exclude others from its use once the research is disseminated.

Public goods are an example of market failure. That is, the economic market cannot properly price them, because the benefits cannot be assigned to particular individuals. Therefore, the purchase of public goods is generally a decision made in the political marketplace.

The expected outcome of social science research is typically a public policy program, legislation, regulatory rule making, or a judicial decision. Some level of government, in response to this research finding, implements a policy that results in a new program, the elimination of an old one, a significant change in an existing program, or a significant change in a law or interpretation of law. One presumes that positive net benefits to society would be “returns,” but how does one determine what these benefits are? Clearly, there are benefits to social science research in general, because society continues to fund it, albeit at different levels in different places and times.

Both *ex ante* and an *ex post* evaluations of research are necessary to determine the returns to policy-oriented research. There must be an *ex ante* evaluation of potential benefits in order to determine whether research should be funded initially. Then, there must be *ex post* evaluations to determine if additional research should be funded, and then further *ex post* evaluations to determine whether the research has paid off and whether it should be given additional funds. These further *ex post* evaluations are often based upon evaluating programs that are put into effect as a result of the research.

Because benefits of social science research may accrue quite slowly, methods used for an initial assessment of benefits from completed research may be somewhat different than the methods employed when one is able to more fully evaluate the results. However, if one waits until all costs and benefits are fully measured before proceeding, start-up costs must be re-incurred, and institutional knowledge may be lost.

PROGRAM EVALUATION

Program evaluation is defined by Wholey as a systematic assessment of the performance, the outcomes, and the impacts of public and nonprofit programs and policies. However, linkages between specific activities and subsequent economic or social outcomes are difficult to measure.^[1] Systematic analysis is not undertaken nearly as often as it should be. Evaluations are not always welcomed, carry risks, use scarce resources, and are often a low priority for programs. Program evaluation has a long way to go before it becomes a routine practice.

The evaluation of the research that goes into developing programs is necessarily a step removed from the program evaluation process. It is a rare event that a program is adopted exactly as the original researchers intended. What is more likely is that a program will bear only a resemblance to the concepts that were originally envisioned. A program must pass through the political process before being implemented, while the research may proceed with somewhat less regard as to what is politically feasible. Benefits may be slow to accrue, and the “law of unexpected consequences” may produce commensurate costs to go with these benefits. Hence, measurement must always be uncertain.

The fact that uncertainties abound should not distract from the goal of evaluating social science research. Policy makers demand accountability for the use of scarce funds by those who carry out programs. With this goal in mind, various literatures that may be of use in assessing the benefits of social science research, proposing a limited theoretical framework to use to select an appropriate method of evaluating research will be drawn upon. The political influences,

biases, and difficulties in measuring the benefits of social science research will be explained. Methods that are used in other evaluation programs will be explained and analyzed to determine their efficacy in evaluating the benefits of this research.

Existing Literature

The literature on measuring the benefits of policy-oriented social science research is practically non-existent, but there is a growing body of public administration literature on program evaluation. Studies and methodologies applicable to research and development (R&D), and basic science research evaluation, as well as policy analysis literature are also available. There is no theoretical framework within which to place quantitative tools for measuring the output of scientific inquiry, although there is comprehensive literature that examines the issue of calculating returns to scientific research and R&D (see Refs.^[2,3]). These literatures include empirical work as well as instruction as to the methodologies underpinning the work. Some generalized theory is available in the program evaluation, scientific research, and policy analysis literature. This will form a large portion of the basis for the recommendations for social science research evaluation theory and practice that are considered here.

The Political Setting of Social Science Research

Social science research has the goal of influencing policy decisions made by government. Often, the government it is attempting to influence funds it. Due to the public good aspects of social science research, profit-seeking interests rarely fund it (an exception being advocacy research, as discussed earlier).

Let us trace a social science research project from start to implementation. First, the researcher is likely to take an interest, because existing literature in the researcher's field or public information diffused through the popular media acknowledges that an unsatisfactory situation exists or is projected to develop if not addressed with due diligence. Funding is made available through a government program or private grant, and the researcher competes for it. The researcher completes the project according to a schedule and presents the evidence in the form of a report or study to the agency or foundation. The research recommends a specific project to be implemented. The study is generally published and is announced to the researcher's professional peers. The popular press may pick it up and diffuse it to the public.

The next step is that a legislator or government executive, viewing it as something that is attractive to his or her constituents, takes an interest or a government

agency or outside group recommends legislation to carry out the program. To the extent that the program creates winners and losers or draws significantly upon the resources of the public, there will be a political battle to modify or defeat the program. Legislators will pack the legislation with their own amendments, designed to create advantages for their constituents or to mitigate damages that the proposed program will create. The legislation that finally becomes law may not implement the program in its entirety or may change the program significantly from that which the researcher proposed. Details of implementation are usually left to the agency in charge. More changes to the program may come from within the bureaucracy or as the result of a public rule-making process.

There are a few evaluation methodologies that focus directly upon research without regard to its results on society at large. However, no matter how vexatious it may prove to be, a results-oriented program to measure the benefits of research must at some point contend with the final product—the tangible results of a program.^a

The goal is to measure the benefits of the research in a quantifiable manner. However, the benefits do not often begin to flow with the performance of the research. Usually, a specific focus that takes the form of a policy program, which may be heavily modified prior to implementation, is necessary to produce benefits from the research.

The Uncertain Relationship of Research to Policy

While policy-oriented social science research rarely, if ever, gets translated directly into policy in its entirety, there are other things that evaluators must be concerned about as a prelude to the determination of how to measure its benefits. Assuming that the particular research in question is in fact propitious, evaluators are still faced with a number of problems beyond the control of the researchers. Good research may not become policy because of laws, institutions, prevailing culture, and opposition by interest groups or the public at large to the proposed program. As Quade and Carter accurately stated, "We may be able to design an efficient system on paper, but as of yet we have no algorithms for finding ways to overcome the

^a*Program* is used in a broad sense here. As is true in physical and mathematical sciences, there is social science research that is undertaken as fundamental research, whereby the goal is to acquire basic knowledge. This research is among the riskiest in the portfolio, with uncertain payoffs that tend to accumulate in the long term if at all. The benefits of this research are extraordinarily difficult to calculate, and more failure is expected at the riskier end of a portfolio, but the end result of the research should be programs.

resistance offered by tradition, legal restrictions, and a host of privileged interests that inhibit radical or even morphological change.”^[4] Competent research may be translated into policy, but the underlying conditions that the research is based upon may change. Finally, good research may be translated into policy, but unanticipated consequences may negate the positive aspects of implementation. Should research that is not used for practical purposes be evaluated for its benefits to society? Unless observers can readily identify its benefits to society or it can be evaluated in a wholesale fashion with similar research, it probably should not be. The ultimate social test of information commissioned by investors in research is its third-party utility.

Biases in Social Science Research

While research inquiries in the arena of the social sciences that are relatively value free exist, they are of far less research interest than those that are value laden. Research assumptions are often highly subject to whatever school of thought the researcher subscribes to, which, in turn, is dependent on a particular political belief or value system. Thus, social science research is often used as ammunition in political wars. Furthermore, research is subject to bias and conflict of interest, at times discovering what the financier of the research wishes to find rather than determining the correct solution to the research questions (if one correct solution indeed exists). Another variation of this conflict of interest is that in-house analyses may favor solutions that confer more resources upon the analysts. Pursuit of fame is another source of research bias. Publication bias often affects research by encouraging scientists to emphasize efforts on new approaches rather than on perfection of old methods. Data mining, or the act of fitting as many alternative equations as there are alternative subsets of potentially explanatory variables, and then picking the best data according to the researcher's criteria invalidates conventional statistical tests. However, those who evaluate the research do not necessarily know if data mining has taken place. A more serious form of data mining is the reporting only of results that the researcher wishes to report, while earlier data runs that may refute the hypothesis being tested are left on the cutting-room floor. There is simple careless, haphazard, and hurried research to contend with. There is fraudulent research and the manipulation of numbers, which are rare exceptions. A project will also require judgments to be made about the direction the research will take at critical paths when options are available.

Why does bias matter in determining how social science research should be evaluated? It has been noted that our evaluation tools are inexact, benefits may

accrue slowly, and social science is value laden. In early stages of evaluation, an individual makes inferences as to whether the research will be productive without programs in place to produce tangible results. The subjective nature of much of social science research carries over to our measurement tools and requires that we be alert to bias in the research.

Designing Social Science Research Evaluation

A design is necessary to measure the benefits and otherwise evaluate social science research. In carrying out social science research evaluation, one must first determine the purpose of the analysis. Will it be conducted to determine if the research is profitable for society, or at least for the financier? Is it to decide whether further research in the field should be funded? Next, a clear, precise, and manageable process designed to elicit information about the research to be analyzed needs to be created. Following this, the analysis must clearly define exactly what is to be measured. Research is but one step in a process, and the actual research must be isolated from the program that implements it. The subject research must also be separated from related research, as well as the rest of the surrounding policies and processes to analyze it effectively. Whether the evaluation analysis is to cover one particular item of research or analyze a group of projects in tandem must be determined. If the target research is a group of projects, it must be decided whether one evaluation methodology or one mix of methodologies will serve to measure the entire range of research. After isolating the research, a metric must be designed in order to measure or rank it against a scale. The users of the research must be clearly defined. While this may seem obvious, there may be multiple users and spillover effects. New knowledge may enhance the value of old, ignored, used up, or simply unrecognized research by lending new life to previous research results. This effect, if it is present, should be captured in any measure of benefits.

How rigorous must the analysis be? Rigor in program evaluation can be costly to achieve. The same is true in measuring the benefits of social science research. Therefore, the rigor of the specific analysis should be defined prior to undertaking the analysis.

An empirical method of analysis that will accomplish the above program must be chosen. The analysis must be carried out according to procedure with as little bias as possible, and results of the analysis must be reported clearly and precisely. This report must also specify the limitations of the evaluation methodology.

With this framework in mind, let us proceed to the “nuts and bolts” of the evaluation process. The available methodologies generally fall short of the

theoretical mark in actual operation. The ability of an evaluator to isolate a particular body of research is questionable. Rigor is a matter of judgment. In fact, the evaluator's judgment, and sometimes the judgments of others, is a crucial element of every available methodology.

The First Step in the Process: Replication of Original Studies

While replication is used extensively in science and technology research, its use in social science is paltry. Replication is much more difficult in the realm of social science, where controlled experiments are generally not available as they are in the purer sciences. Reality within social science is a social construct, it is unstable, and it is subject to continuous change. It is more dependent on culture than is pure scientific research. The fact that social sciences are value laden makes the task of evaluation harder.

One might fairly ask why replication should be used to determine the benefits of social science research, because replication is further research rather than research evaluation. But, it assures that research that at least initially appears to be beneficial is correctly reporting results prior to program development and prior to further evaluation of the research.

Replication is often left to graduate students in the social science arena, if it is conducted at all. The system of professional honors and rewards in the social science system does not place a high value on replication. The ability to reproduce a researcher's methods in order to validate results is a clearly recognized requirement of scientific inquiry and is *de rigueur* in the sciences. It should become a part of social science research evaluation as a first step in establishing the benefits of particular research.

The simplest replication is to repeat the experiment exactly using the same data set. This is often possible if the research performs statistical analyses on a particular data set consisting of historical events. One may also consider multiple cases as one would consider multiple experiments. In this case, literal replication is defined as the selection of a case, so that it predicts similar results. Theoretical replication produces contrary results but for predictable reasons. The purposes of conducting replication studies are several. First, they provide useful checks on the work of the original researchers, particularly to provide evidence as to whether the procedures were carried out as described in the replicated paper. Second, if a number of different procedures are used in addition to the ones originally used, evidence of whether different methods produce different results is provided. If different methods do not produce different results, the study is replicated

successfully. If they produce different results, it is necessary to discover why. And, evaluating the initial research is a futile exercise if there are major problems with the original inquiry, so it is useful to examine the work for accuracy before proceeding with further analysis.

Most Evaluation Methods Can Be Subjective and Difficult to Quantify

Having identified replication as the first necessary step in the evaluation process, a number of methods of evaluation are discussed below. These methods are not equal; some are better than others for particular tasks. Some will be rejected for most uses in evaluating social science research, but will be discussed because they are available. Most of the methods available are judgmental, subjective, and offer little in the way of quantifiable results that will satisfy those who wish to have a simple metric by which to accept or reject. This is unavoidable with the tools we have just as it is unavoidable in the original research we seek to evaluate.

Bibliometrics

Bibliometrics, or the measurement of published materials such as citations and publication counts, is a tool that is often used as a proxy to measure returns to R&D spending and evaluation of scientific programs. It has been used since the turn of the twentieth century. Garfield and Price pioneered the modern use of bibliometrics.^[5,6] This method is used extensively in the British university system, by the U.S. National Institutes of Health, and by the National Science Foundation. It is a measurement of research others believe to be important, because citations are an indication of a researcher's familiarity with a particular literature and the relevance of a particular article or study to a researcher's own work. There are a number of methods used to perform an analysis of citations. These range from simple counts to linking citations to each other.

Bibliometrics suffers from a number of flaws. The esteem in which a particular author holds a cited paper cannot be garnered from references of citations. Bibliometrics cannot measure quality. The discredited cold fusion paper of Pons and Fleischmann was among the top 10 of the most heavily cited papers in the scientific literature for several years. The quality of the article in which the citation appears cannot easily be measured. Some disciplines are more publication oriented than others. Finally, this analysis cannot measure benefits to society at large from the research undertaken.

One of the suitable characteristics of bibliometrics, from the standpoint of evaluation methodology, is that

it imposes measurement upon the original research rather than the programs that may result from it. However, given its flaws, it may be useful as a supplement to other methods but cannot stand alone as a method for evaluating social science research.

Similar Peer Review Measures

Measures similar to bibliometrics include convening panels of experts for evaluation based upon peer review. First used in 1665, it is the earliest evaluation method known. Peer review relies upon the expert judgment of colleagues within the same field. Many R&D laboratories as well as government agencies use it. Social science research contracts are likely to be awarded as a result of peer review in the competition process. There are a number of different forms of peer review. The reader is referred to Bozeman and Melkers for a review of the different methods as well as guidelines for enhancing this evaluation.^[7]

The results of these measures are highly dependent on the choice of reviewers. Furthermore, this methodology does not satisfy the yearning for a less judgment oriented, more direct, and more empirically based means of measurement. Peer-based appraisals such as enumerating awards and other recognition from professional societies and patent and copyright counts (which have limited use for social science research) provide a quantitative means of measuring output, but not a scalable one. Peer review methods may be used along with other methods but cannot stand alone as satisfactory means of measuring social science output.

Case Study Methodology

“A case study is an empirical inquiry that: investigates a contemporary phenomenon within its real-life context; when the boundaries between phenomenon and context are not clearly evident; and in which multiple sources of evidence are used . . .”^[8] Case study methodology makes use of historical comparative data to tell a story that is much richer in detail than statistical analysis, which by its nature must be somewhat abstract.

Case study methodology is a viable tool for the evaluation of social science research when carefully applied. The evaluator can tell a story of how the research is translated into policy and how the policy then carries out the goals of the research. Modeling and advanced statistical methods are rarely used, but statistical data in the form of charts and tables are expected. The methodology may be qualitative, quantitative, or both.

The primary weaknesses of case studies are that there is potentially a lack of rigor, possibly little basis

for scientific generalization, and case studies sometimes take too long and result in massive, unreadable documents. To overcome these weaknesses, the evaluator must be specific about the research question and develop a rationale for the methods used and how these methods address the specific evaluation needs. Examining successful and unsuccessful projects may be useful, but this may use up resources that could be put to better use in evaluating research that at least gives the first impression of being successful.

Delphi Method

The Delphi method, first used in an attempt to improve betting scores at horse races in 1948, was developed at the Rand Corporation in the 1950s and 1960s as a method to increase the accuracy of forecasts. It involves picking an expert panel, which is surveyed through a questionnaire. The questionnaire is evaluated and then returned to the experts with the findings presented statistically. They are allowed to change their opinions to reflect new information and the judgments of their colleagues (but the experts are not allowed to have contact with each other). This process goes through a number of iterations until opinions converge. Convergence can be dependent on peer pressure toward conformity rather than rational processing of information. The Delphi method presently offers little for social science research analysis that cannot be gained through the use of other methodologies.

More Direct Methods: User Evaluations

User evaluations in the context of social science research evaluation entail surveying the actual users of the research to elicit information on its value. This is a costly form of analysis that may involve conducting interviews or mail or telephone surveys and the development of a survey questionnaire. The metric is ordinal rather than cardinal. There may be an inherent conflict of interest in surveying users, particularly if they receive free or low-cost benefits. They have a vested interest in expressing satisfaction in order to keep the benefits flowing.

A survey is highly dependent on the biases of those surveyed as well as those biases inherent in the questions posed to the sample of respondents. Given the costs, survey methods do not appear to be among the best means of conducting social science research evaluation other than to determine the satisfaction levels of the particular beneficiaries, particularly if the benefits to society are of greater interest.

Focus groups, small group discussions conducted with the users of the research, are another means of user evaluation. This is somewhat less costly than

survey methods, but selection of participants is not often random, and the output may be difficult to present in a systematic fashion. This technique should be reserved for program evaluation and customer service, when the provider wishes to improve delivery of its product or service.

Cost-Benefit Analysis or Measurement of Social Rates of Return

Cost-benefit analysis, which reached its peak of popularity in environmental studies, seeks to measure the benefits and the costs of a given project in a systematic and rational manner. The logic underpinning of cost-benefit analysis is quite simple. One calculates the benefits of a project or program in monetary terms. Then one calculates the total costs and compares the two. Alternatively, one may calculate and compare marginal costs and benefits. Financial methods such as the internal rate of return (the discount rate that makes the present value of estimated benefits equal the present value of estimated costs) are used in conjunction with this methodology.

While this is rudimentary in principle, it poses great challenges in practice. Quantifying costs and benefits may prove elusive. Particularly thorny is the question of determining the value of human life and health. The analyst makes judgments and critical assumptions that are buried in the calculations. Furthermore, the process is prone to manipulation by those determined to reach a particular outcome. The discount rate is never known with certainty and may be subject to manipulation. Finally, externalities are difficult to estimate with simple cost-benefit approaches.

While formal cost-benefit analysis has lost much of the glamour it had two decades ago, it is still a useful tool in policy-oriented research evaluation, as long as the premises upon which the evaluator makes judgments and calculations are clearly spelled out, even though it might prove to be difficult to separate the results of the research from the results of the implementation program. Although the analysis may have lost some of its luster over the years, all methods of evaluation require the analyst to make a determination of benefits vs. costs.

Statistical Methods: Regression Analysis

Statistical regression analysis takes the form of the standard regression equation:

$$Y = \alpha + \beta X + \mu$$

where Y is the dependent variable, α is a constant, X represents the independent variables with coefficient

β , and μ is the error term. The method fits a line or curve by the statistical means of least squares. It is a well-known, but intricate, statistical technique.

Popper refers to analyses conducted upon R&D using regression methods as production function analyses, because they involve the use of production functions in a regression equation.^[9] A production function measures the change in output due to a change in an index of inputs. The empirical production function is estimated by the specification of various models.

This method has been used with reasonable success in R&D research.^b Assessing the benefits of specific research by use of production functions may prove to be highly elusive. There is an advantage in using it to assess the benefits of R&D in private markets that do not exist in public markets—the existence of measurable input to firms and measurable output in the form of goods and services produced. However, it is possible to roughly model the results of social science research in the following manner: Use a time series of program budgets minus personnel costs as proxies for capital costs, personnel costs as proxies for labor, and the variable that the research is designed to act upon as the output variable. In particular, one may be quite interested in determining whether the research in question leads to increasing returns to scale.

Regression analysis does not need to be production function oriented in order to be useful in evaluation practices. One may partially isolate the original research from the program by properly selecting variables if multicollinearity does not present an insurmountable obstacle.

The pitfalls of regression are that it must relinquish rich details in order to create a workable model, the model may be mis-specified, and it may create a false sense of quantitative certainty. The evaluator must be clear on the variables selected and the reasons they were selected.

Robust and Substantively Weighted Regression Analysis

Oftentimes data sets contain “outliers” or individual observations that are significantly larger or smaller than most in the sample. There are a number of methods used to constrict their effects on the analysis without discarding them altogether without valid reason to do so. These methods may be found in most modern statistical texts. In addition, there is a newer method that is just the opposite: substantively weighted regression. This method gives heavier weight to the outliers as it attempts to define “best practices” or best

^bMansfield and Hall discuss the uses and pitfalls of this method in greater detail.^[10,11]

practitioners of a particular program. Primarily a tool of public administration, it also has applicability in social science research evaluation.^[12]

Operations Research Modeling Methods

Operations research modeling techniques have also been used in assessing programs for a number of years. Linear programming is a quantitative methodology that makes use of the mathematical modeling of constrained optimization. An optimal solution is sought, given certain constraints imposed by the model. A number of methods are available beyond simple linear programming. These include goal programming and data envelopment analysis (DEA).

Goal programming is based upon a paper by Charnes et al., it represents an attempt to put the concept of “*satisficing*” into operations research modeling.^[13] The technique puts goals and aspirations on one side of the equation and constraints that must be satisfied on the other. Priorities of individuals and groups may be taken into account by means of goal programming.

While this method does not appear to receive much discussion in the evaluation literature, perhaps because it is associated with applied science and engineering, it is likely to hold some promise as a quantitative methodology for the purposes specified herein. Selecting the researcher’s goals, using a goal-programming methodology rather than selecting the goals of the program, may be a means of isolating the effects of the research from the program.

DEA contains the concept of the production function that was mentioned earlier. Rather than fitting a line in a least-squares fashion, it fits a boundary that contains all points within it (the production possibilities curve). This method is likely to be successful in those cases where production function methodology is appropriate. The use of both methods will increase the rigor of the study, but of course, this has a cost.

Simulation: A More Recent Development in Operations Research

Simulation is a heuristic, probability-based methodology that conducts experiments by proxy using a model and runs that consist of selecting values of uncontrolled variables. This is accomplished by using Monte Carlo analysis, or repeated simulation of a stochastic model to investigate the properties of statistical techniques applied to it. An abstract model, but one that contains enough stylized facts to approach authenticity, is necessary. This technique has a long history in applied sciences, particularly in

defense work. Some advantages are that simulation can deal with uncertainty, it is versatile because it can be run many times, it can reproduce variability that actually occurs in the system being simulated, multiple objectives can be analyzed, and it is a rational tool. The limitations are that there may be a temptation to build a model that is too big and too expensive, and one could proceed with the modeling process only to find out that no one understands the interactions of the variables well enough to build a workable model. Judgment and elements of subjectivity enter into specifying the model as they do in other methodologies. Finally, simulation is based upon limited real-world data rather than the analysis of historical processes using only knowledge of actual events.

Simulation has been most heavily used in applied sciences. It is useful in social science research evaluation when data are hard to come by, or one suspects processes are at work that are extraordinarily difficult to model by conventional means. Additional simulation models involving the use of genetic algorithms, non-linear regression, and other modeling techniques are currently being developed in the growing field of computational economics and by complexity theorists.

Simulation is quite useful to determine system sensitivity and the range of intervention options. The major problem is that it is not based upon actual observed data, although the models may take actual data into consideration when generating scenarios. The output measures potential reality rather than actual circumstances.

Meta-Analysis

Meta-analysis is a fairly new analytical method that summarizes the studies that have the same dependent variable that have already been completed and are found in the literature. The term was coined by George Glass in 1976, who described it this way: “Meta-analysis refers to the analysis of analyses ... the statistical analysis of a large collection of analysis results from individual studies for the purpose of integrating the findings. It connotes a rigorous alternative to the casual, narrative discussions of research studies, which typify our attempts to make sense of the rapidly expanding research literature.”^[14]

CONCLUSION

This article has outlined a rudimentary theory to be used in the application of evaluation methodologies. A number of methods to accomplish a benefits analysis of social science research have been offered. Many are

well-known research methodologies that are already extensively used in conducting social science research and program evaluation. Replication should be conducted as part of the evaluation process prior to reaching the question of whether the research is beneficial. None of the methods presented as potential tools for carrying out evaluations is completely satisfactory insofar as answering our theoretical needs. A mix of methods may prove to be the best approach in many cases. The link between research and application of results is likely to remain tenuous, which means that an investigation into the benefits of social science research will likely remain an exercise in muddling through. Decision makers will find it necessary to select among the evaluation methodologies.

Efforts into improving research benefits analysis should focus upon improving existing methods, especially because the costs of processing large quantities of data have dropped significantly and will continue to drop. In particular, operations research methodologies appear ripe for adaptation to social science research evaluation. A single quantitative solution that stands head and shoulders above the rest is unlikely to be found. Better results are likely to be obtained if programs to evaluate research are implemented rather than if we consume time and resources looking for better means of evaluation. This does not mean that we should not seek to improve our evaluation methods. However, we should not strive to perfect our methods while passing up opportunities to put the tools we have into practice.

Popular Reporting

Joy A. Clay

*School of Urban Affairs and Public Policy, University of Memphis,
Memphis, Tennessee, U.S.A.*

INTRODUCTION

Professional bodies concerned with assuring and promoting high quality government accounting and financial reporting practices, such as the Governmental Accounting Standards Board (GASB) and Government Finance Officers Association (GFOA), view quality financial reporting as an important facet of assuring government accountability (see www.seagov.org and www.gfoa.org, respectively).^[1] Accordingly, state and local governments are encouraged to issue a high quality, comprehensive annual financial report (CAFR) in conformance with generally accepted accounting principles (GAAP). This annual financial report, the CAFR, is increasingly being supplemented with a more stylish and simpler report, the Popular Annual Financial Report (PAFR), aimed at general, “popular” audiences.

Although the simpler report has less technical language and provides less detailed information than the CAFR, the popular report is expected to be credible and present an accurate, objective picture of governmental activity. Popular reports are generally aimed at lay audiences such as citizens, activists, business leaders, civic organizations, etc. who are more interested in gaining a broad understanding of a government’s activities and who often are not versed in, or want to take the time to understand, governmental accounting and bureaucratic language.

CONTEXT FOR THE REPORT: GOVERNMENT ACCOUNTABILITY

Underlying democratic government is an expectation that those in power are held accountable for their decisions and actions. Public reaction to the recent financial and governance scandals in the private sector, such as Enron, and continued public concern about government spending have added increased energy to the public management reform efforts started in the 1980s. A growing consensus on the part of public administration professional groups, including the International City/County Management Association (ICMA), GFOA, GASB, American Society for Public Administration (ASPA), has led these groups to place pressure on governments to expand vehicles and

processes of accountability. Consequently, public agencies/governments are encouraged not just to improve formal evaluation or auditing processes but to assure the transparency of governmental actions, that is, not just to evaluate programmatic results but to regularly report on them to citizens in a way that assures reliable, useful, understandable, and accurate information is being provided to a broad audience. Thus, governments are expected to generate consistent performance data and report it regularly and publicly.^[2] The popular report is one of the vehicles for governments to report on performance/results. The underlying assumption is that regular governmental attention to public accountability will in the short and long term further public trust in and credibility of government as it reduces information asymmetry.^[2]

CHARACTERISTICS OF THE POPULAR REPORT

The most specific guidance available on popular report characteristics is offered by GFOA. In summary, GFOA recognizes that popular reports can be presented in a variety of formats. Specifically, GFOA strongly encourages governments to produce a summary financial report that successfully attends to the following five characteristics:

1. Presents timely information (no later than 6 mo after the close of the fiscal year);
2. Clearly describes scope (defines what is included in the report), providing an explicit link to the CAFR to facilitate further research if desired by the reader;
3. Thoughtfully presents helpful comparative data, for example, trends or benchmarks;
4. Presents a report design/layout that is attractive, engaging, clear, and concise, with a format that avoids technical jargon and includes supportive and summative graphic material such as charts and photographs or narrative material that enhances reader understanding; and,
5. Implements an appropriate dissemination strategy (that is, the distribution approach actually gets the report to the target audience/stakeholders).

An important challenge for governments is this last characteristic, the appropriate distribution of the report. The distribution strategy must balance cost, including production and distribution costs, as well as predict volume, based on estimated readership interest. Increasingly governments make these reports available on their websites (see www.cityofmemphis.org/citizensReport2003 or PAFR award winners' sites at www.gfoa.org). Electronic posting of the popular report not only saves distribution costs but broadens accessibility.

RECOGNITION FOR EXCELLENCE

The Outstanding Achievement in Popular Annual Financial Reporting Award was established by GFOA in 1991 (J. Phillips, personal communication, September 14, 2004). This award recognizes those governments that develop a high quality popular report. Judging by the history of success that GFOA has had with the CAFR award, over 3000 governments annually apply for the CAFR award,^[3] this is a successful means of encouraging innovation and adoption of a high quality financial reporting practice. As with CAFR award winners, governments, specifically the finance and budget offices, winning the PAFR award tend to advertise receiving the award as a prestigious measure of their performance.

GFOA asks judges to assess PAFRs on their overall quality and usefulness, specifically evaluating the report's reader appeal, understandability, distribution methods, and degree of creativity/innovation. A slowly increasing number of governments are applying for the award. For fiscal year end 1996, only 29 governments applied for the award but 55 applied for 1997. More recently, the number of applicants for the award has increased approximately 6% annually (J. Phillips, personal communication, September 14, 2004). GFOA reports that 112 governments applied for the award last year and anticipate 116 next year (www.gfoa.org). The growing list of state and local governments seeking this relatively recent award attests to the number of governments producing this new financial report.

IMPLEMENTATION CONSIDERATIONS

Leadership Responsibility

Before deciding to undertake creation of a popular report, government executives need to make several key decisions, including assignment of responsibility for preparing the report and coordinating data collection, scope of the report content, dissemination guidelines, and cost parameters. Executive leaders will also

need to take into consideration the political ramifications associated with such a report, including degree of involvement of legislative leaders, capacity to continue with the report once started, willingness to receive public feedback, and the ability to present balanced and objective information. Inherently, the popular report is to be a public and accessible document. Thus, both successes and challenges will need to be presented. GFOA states very clearly that "most important, the popular report should establish its credibility with its intended readers by presenting information in a balanced and objective manner."^[3]

Report Tasks

Once the broad framework has been decided upon by government leaders, the work can be delegated to the appropriate unit and staff member(s) and responsibility for collecting the data and preparing the report can proceed. A critical decision rests on the assessment of staff capacity, that is, budget analysts may not have the requisite graphic or stylistic creativity needed to produce a highly styled report. Consequently, leaders may need to seek outside assistance, especially to create the cover design and layout, decisions which may add to the overhead cost of the report as the design becomes more sophisticated. If the governmental entity wishes to seek the GFOA excellence award, the report also needs to reflect innovative and creative practice. Consequently, leaders will need to commit time and attention to the project. This may present a challenge since these same leaders generally have the responsibility for producing the CAFR. All of these managerial decisions rest within budget constraints and feasibility considerations.

As with any report, the lead narrative and graphic information should capture the essence of the governmental unit. With the PAFR, this approach must be pleasing to the eye. Key content decisions include finalizing the scope of the report (what will be included, breadth and depth), how best to link to the CAFR, appropriate inclusion of insightful trend and/or benchmark information^[4-6] as well as graphic/photo illustrations add to the attractiveness and understandability features of the report but also to the cost of the report. The use of color enhances the presentation quality of the report but adds to production costs.

A significant feature of the PAFR also can be the inclusion of results of citizen satisfaction information. Integrating an assessment of citizen satisfaction with programmatic performance reporting will more comprehensively address various issues related to public accountability.^[7]

The PAFR, especially if available on the government website, offers the opportunity for place marketing.^[8] This makes the section that introduces the

community context and strategic visioning of the community of particular value. The popular financial report, thus, can serve as a promotional vehicle that communicates the government's assets and the essence of the community to readers. Achieving a balance between substance and presentation is a measure of a government's ability to present policy, performance, and programmatic information in a manner that encourages readers to actually read the report and thus, better understand their government.

CONCLUSIONS

As with all government reports, public administrators need to attend to data quality issues including any problems with reliability and validity of data, and objectivity. Although in "popular" format, the popular report is an official government financial report.

The decision to broaden the availability of government financial reporting recognizes that citizens are stakeholders in their community, not just customers of services, and should be able to expect a return on their tax dollars.^[9] The PAFR presents an opportunity for governments to proactively provide information that addresses policy, program, and performance accountability. The value of the PAFR lies in the nature of the report, that is, governments must present this information in human terms, not shrouded in technical and complex financial or programmatic language. To engage in the PAFR process, encourages creativity on the part of budget and finance officials and reinforces the need to be able to articulate a community

context, the vision of the community, achievements to date, and artfully position challenges.

Portfolio Theory

Richard L.B. LeCompte

Wichita, Kansas, U.S.A.*

INTRODUCTION

Portfolio Theory, also known as Modern Portfolio Theory, focuses on the construction and selection of optimal portfolios of risky assets by risk-averse investors. The origin of modern portfolio theory is the seminal work of Harry M. Markowitz in the early 1950s. This work was published in his 1952 paper, *Portfolio Selection*.^[1] His body of work on portfolio theory resulted in him being awarded the Nobel Prize in economics.

Today, the work of Markowitz, and the extensions of it, provides the basis for portfolio theory as well as an understanding of the relationship between the risk and expected return on securities or assets held in a portfolio of assets. Utilizing his methodology, the investor seeks the maximum expected return for a given level of risk or the minimum risk for a given level of expected return. He altered the focus of investment analysis away from individual security selection toward investment analysis concentrated on diversification concepts and the impact of individual securities on a portfolio's risk–return characteristics. In Markowitz's formulation, efficient portfolios are formed by choosing an asset based upon its interaction with other assets in the portfolio, not on the basis of its stand-alone performance. The evidence of his impact is the widespread application of his research in quantitative portfolio management, risk management, and asset valuation. The acceptance of portfolio theory by academics, financial practitioners, and investors over the past 50 years has provided much of the impetus for the growth in the use of passive portfolio management techniques and the tremendous popularity of index funds.

Portfolio theory also forms the basis for a wide variety of academic research in diversification theory, portfolio selection, market efficiency, and capital market theory. Most notably, Markowitz's optimal portfolio selection methodology is utilized in the development of Capital Market Theory, which led to the conception and derivation of the Capital Asset Pricing Model (CAPM). CAPM was developed independently during the mid-1960s by William F. Sharpe,^[2] John Lintner,^[3] and Jan Mossin.^[4] CAPM research, in turn, formed the building blocks for another important asset pricing model, the Arbitrage Pricing Theory (APT). The APT was derived by Stephen A. Ross^[5] in 1976.

OVERVIEW

Portfolio theory is defined as quantitative analysis for optimal risk management.^[6] Markowitz's portfolio theory is based upon a mean-variance optimization (MVO) process that searches for efficient portfolios. An efficient portfolio is one that provides minimum risk for a given level of return or maximum return for a given level of risk. Rational, mean-variance optimizing, investors will construct optimal asset portfolios by determining the best risk–return opportunities available from feasible investment portfolios and then choose the best portfolio from that feasible set.^[7] A key contribution of Markowitz's research is that it mathematically quantifies, for the first time, the benefits of risk reduction achieved through portfolio diversification. Moreover, his work demonstrates that optimal diversification requires the selection of securities based upon their interrelationships or comovements, not just a random selection of a large number of securities. The MVO algorithm generates “efficient” portfolios by minimizing risk subject to a given level of expected return or maximizing expected return subject to a given level or risk. The optimization process assumes that risk-averse investors consider risk to be the variability of expected asset returns, measured by variance. These rational risk-averse investors select investments using only mean-variance criteria, i.e., given two assets with equal expected returns, they will choose the one with the lower risk, or given two assets with equal risk, they will choose the one with the higher expected return. The required inputs into the optimization model are the expected returns for each asset, the variance of each asset, and the covariances between these assets, where covariance is the statistical measure of the comovement of two securities' returns through time. Positive covariance between securities indicates that their returns move in the same direction; negative covariance indicates that the securities' returns move in opposite directions. The size of the covariance measure indicates the degree of comovement between securities.

Markowitz shows that the relevant risk of a security is determined by the covariance of its return with that of a diversified portfolio or market index, not a security's own variance in isolation. Portfolio theory provides investors with appropriate measures of portfolio and security risks and a methodology for

accomplishing optimal security selection and portfolio construction. At the same time, it quantifies the importance of portfolio diversification.

MEAN-VARIANCE FRONTIER

The mean-variance optimization process generates an efficient frontier, as shown in Fig. 1, consisting of portfolios that “dominate” the ones lying below and to the right on the basis of expected return or standard deviation.

These dominant, or efficient, portfolios are ones for which no other asset or portfolio of assets offers higher expected return with equal or less risk, or offers lower risk with equal or greater expected return. The optimal portfolio for an individual investor is the efficient portfolio that provides the highest utility based upon risk–return preferences. The utility curves, shown in Fig. 2, indicate the investor’s willingness to trade expected return for risk, while the efficient frontier shows the investor’s opportunity set, or ability to trade risk for expected return. The point of tangency between these two curves indicates the optimal portfolio choice for the investor in the MVO framework. This point of tangency identifies the efficient portfolio that provides the rational risk-averse investor with the highest utility or level of satisfaction.

EXPECTED RETURN AND RISK

To execute MVO, one first needs to compute the expected return for each asset and portfolio. The expected return on a portfolio is the weighted average of the expected individual returns of the assets held within it. The weight assigned to each asset is the

Fig. 1 Efficient set of portfolios.

Fig. 2 Optimal portfolio selection without risk-free asset.

asset’s value as a percentage of the total portfolio value:

$$E(R_{\text{portfolio}}) = \sum_{i=1}^n X_i E(R_i)$$

where

X_i = the percent of the portfolio invested in asset i ,
 where the sum of the weights equals 1 (or 100%).
 $E(R_i)$ = the expected return for asset i .
 $E(R_{\text{portfolio}})$ = the expected return for the portfolio.

The second component required in the optimization process is a measure of portfolio risk, which is the variance of an asset’s expected returns. This is a statistical measure of the dispersion of possible returns around the mean expected return. As shown below, Markowitz’s measure of portfolio risk is a weighted function of the variances and covariances of the individual securities held within it and is computed as follows:^[8]

$$\sigma_{\text{port}}^2 = \sum_{i=1}^n w_i^2 \sigma_i^2 + \sum_{i=1}^n \sum_{\substack{j=1 \\ i \neq j}}^n w_i w_j \rho_{ij} \sigma_i \sigma_j$$

where

σ_{port}^2 = variance of portfolio.
 w_i = proportion of total investment in security i .
 ρ_{ij} = correlation coefficient between security i and security j .
 σ_i^2, σ_j^2 = variance of securities i and j .
 $\rho_{ij} \sigma_i \sigma_j$ = the covariance of securities i and j .

From this equation for portfolio variance, it can be seen that when an investor invests in more than one

asset, the relevant risk of the portfolio is a function of the percentage of the portfolio invested in each asset and two distinct risk components. One of these components measures the contribution to portfolio risk by each asset's own variance. The other risk component measures the sum of the weighted covariances between the assets within the portfolio, i.e., how the returns of the assets move together. The first component is diversifiable security-specific risk, and the second is non-diversifiable market risk. The equation also demonstrates that the relevant risk of a security held in isolation is its own variance, because the covariance term in a one-asset portfolio will be equal to zero. But, as the investor diversifies by increasing the number of securities in the portfolio, the value of the first term on the right-hand side, a weighted average of individual security variances, diminishes rapidly. And in an optimal efficient portfolio, diversification will virtually eliminate this component, so that the investor's remaining risk is that attributable to market or systematic risk that cannot be diversified away. The greater this systematic risk, the greater will be the investor's expected return. In equilibrium, security markets will only reward the investor with higher-risk premiums for the systematic risk contained in a portfolio.

It can be shown theoretically and empirically that it takes only a small number of randomly selected securities in a portfolio to eliminate most of the non-systematic risk. Meir Statman's empirical research^[9] indicates that an investor must include between 30 and 40 stocks in their portfolio to eliminate non-systematic risk. Other research has indicated as little as 15 to 20 individual securities would accomplish the same task. The conclusions from portfolio theory show, as in Fig. 3, that diversifiable risk is reduced as securities are added to the portfolio, and that the

relevant, remaining risk is systematic and cannot be diversified away.

PORTFOLIO VARIANCE

Using the formula above, variance in the Markowitz two-asset portfolio is calculated as follows:

$$\sigma^2 = x_A^2 \sigma_A^2 + x_B^2 \sigma_B^2 + 2x_A x_B \rho_{AB} \sigma_A \sigma_B$$

where

$$x_A + x_B = 100\%.$$

$$\sigma^2 = \text{variance of the two-asset portfolio.}$$

$$x_A^2 = \text{percentage squared of the portfolio invested in an asset A.}$$

$$x_B^2 = \text{percentage squared of the portfolio invested in an asset B.}$$

$$\sigma_A^2 = \text{variance of return on security A.}$$

$$\rho_{AB} = \text{correlation coefficient for securities A and B.}$$

$$\sigma_B = \text{standard deviation of security B.}$$

$$\sigma_{AB} \sigma_A \sigma_B = \text{covariance of securities A and B.}$$

And, portfolio variance with three assets is computed as follows:

$$\begin{aligned} \sigma^2 = & x_A^2 \sigma_A^2 + x_B^2 \sigma_B^2 + 2(x_A x_B \rho_{AB} \sigma_A \sigma_B) \\ & + 2(x_A x_C \rho_{AC} \sigma_A \sigma_C) + 2(x_B x_C \rho_{BC} \sigma_B \sigma_C) \end{aligned}$$

The progression from two-asset to three-asset portfolios shows that as the number of securities in the portfolio increases, the number of covariance terms increases substantially, as do the computational complexity and estimation problems of the model. In the Markowitz setup, one can easily derive the minimum-variance portfolio for a small number of assets. For portfolios with large numbers of assets, however, the MVO process and construction of efficient portfolios becomes impractical, because the variance equation becomes quite complex, and the calculations become unwieldy due to the number of covariance terms that must be estimated to serve as inputs in the optimization process.

CAPITAL MARKET THEORY AND THE CAPITAL ASSET PRICING MODEL

The CAPM, developed by Sharpe, Lintner, and Mossin in the 1960s, provides an extension of Markowitz's portfolio theory framework and introduces a general equilibrium asset-pricing model with significant practical applications and theoretical implications. The CAPM optimization process for security selection is far less complex and reduces the number

Fig. 3 Optimal portfolio selection with risk-free asset.

of calculations markedly compared to Markowitz's selection process for efficient portfolios. This simplification results from the CAPM's use of pair-wise comparisons of security covariance with the "market portfolio," rather than using the full covariance matrix between all asset pairs, as in Markowitz's optimization.

CAPM extends the Markowitz portfolio model through the introduction of a risk-free asset. Now, the investor is faced with choices among many risky assets and a risk-free asset. By definition, the risk-free asset has zero risk and zero covariance with the risky assets, i.e., its return is not correlated with the returns on risky assets. The optimization still requires the derivation of an efficient frontier of risky assets, as in Markowitz's optimization. However, with the introduction of the risk-free asset, the optimal portfolio is found at the point of tangency with a line drawn from the risk-free rate on the y-axis to the portfolio on Markowitz's efficient frontier that provides the greatest reward per unit of risk, as shown in Fig. 4.

This line creates a new efficient frontier depicting all the risk-return combinations for portfolios consisting of the risk-free asset and the market portfolio. This new set of efficient portfolios dominates all the portfolios on the Markowitz efficient frontier. These portfolio combinations create a Capital Market Line (CML) from which all investors will make their portfolio allocations between the risk-free asset and the market portfolio. Portfolio selection is a two-step process: 1) determining the optimal risky portfolio; and 2) choosing the allocation between risky and riskless asset. The second choice is based upon one's risk tolerance, and investors' allocations will differ only by the proportion of their portfolio invested in the risk-free asset. A key facet of the CAPM is that all investors choose the same risky portfolio, which is the market portfolio. In theory, the market portfolio includes all risky assets with the weight of each asset set in proportion to its

market value. In practice, however, many practitioners use a broadly diversified index such as the S&P 500 as a proxy for the "market" of all risky assets. The characteristic inducing all investors to choose the market portfolio is that it is completely diversified. Therefore, it contains only systematic risk, because all non-systematic risk is eliminated through diversification.

Sharpe shows that, in equilibrium, investors will choose the market portfolio in combination with the risk-free asset, because it provides them with the highest return per unit of risk. This equilibrium outcome paves the way for the derivation of the CAPM and the resulting Security Market Line from which expected asset returns could be determined.

SECURITY MARKET LINE AND ASSET PRICING

The CAPM equilibrium shows that an asset should earn a risk-adjusted return that is a function of the risk-free rate, the asset's Beta, and the expected return on the market. The resulting pricing relationship is known as Security Market Line (SML). Algebraically, the SML is as follows:

$$E(r_i) = r_f + \beta_i(r_m - r_f)$$

where

$E(r_i)$ = expected return on asset i .

r_f = the risk-free rate.

β_i = Beta of asset i .

r_m = expected return on the market.

If markets are efficient, all securities will be priced using the equation above.

A security's Beta is calculated as follows:

$$\beta_i = \frac{\text{COV}(R_i, \tilde{R}_m)}{\sigma_m^2}$$

where

$\tilde{R}_m$ = return on the market index.

σ_m^2 = the variance of the market return.

R_i = return on the security i .

COV = covariance.

For any asset i , the Beta is calculated by dividing the covariance of the returns on asset i and the market portfolio by the variance of the market return. It is a measure of the comovement of a security's return with the expected return of the market portfolio. The CAPM defines the Beta as the appropriate measure of a security's systematic risk for assets held within

Fig. 4 Portfolio risk compared to number of securities in portfolio.

the diversified market portfolio. In theory, security Betas should be derived using *expected* return data from the individual securities within the portfolio. In practice, however, this is often done using historical security returns compared to an index such as the S&P 500. The importance of a security's Beta is in determining the required rate of return on a security and its corresponding value or price. Security Betas are widely reported and used extensively in investment and security analysis as a measure of volatility or risk. For a portfolio of securities, the portfolio's Beta is simply the weighted average of each asset's Beta.

The CAPM's contribution to portfolio theory is that it quantified the appropriate risk–return relationship for securities held within a portfolio in an efficient market. It also provided investors with a standardized measure of a security's systematic risk, i.e., its Beta. This equilibrium pricing model for individual securities allows one to compute the expected or required return for a risky asset in equilibrium, and from that, security prices and valuations can be performed. Implications from CAPM equilibrium include that there is no tendency for underpriced or overpriced securities and no expectation of superior performance from active portfolio management strategies. These implications result from the assumption that information will be fully priced and reflect all available relevant information, and the resulting equilibrium sets prices at their expected value in a diversified portfolio. This is known as market efficiency.

ARBITRAGE PRICING THEORY

The competing theory of asset pricing in the portfolio context is a multifactor equilibrium pricing model introduced in 1976 by Stephen A. Ross. It is known as the Arbitrage Pricing Theory (APT). It allows for multiple sources of risk premiums, or factors, whereas the CAPM is a single-index model based upon the market return and the security's Beta. The derivation of the APT does not require that investors select assets using mean-variance rule or that those investors are risk averse. However, using Ross's Arbitrage pricing construct, the APT also generates a linear relationship between risk and expected return.

APT allows for the pricing of risk premiums associated with multiple factors 1 through k as shown below:

$$\begin{aligned} E(r_i) = & rf + \beta_1(\text{risk premium for Factor 1}) \\ & + \beta_2(\text{risk premium Factor 2}) \\ & + \beta_3(\text{risk premium Factor 3}) + \dots \\ & + \beta_k(\text{risk premium Factor } k) \end{aligned}$$

where

$E(r_i)$ = expected return on security i .

rf = the risk-free rate.

β_k = Beta of security k for a particular risk factor.

Under APT, the expected return is determined by the aggregate of a number of systematic factors. Investors will be compensated for each non-diversifiable source of risk associated with a particular security. If factors 2 through k are 0, and the common factor generating security returns are the “market” portfolio, then the APT and CAPM will yield similar results and conclusions. The APT has fewer restrictive assumptions than CAPM, but it requires competitive capital markets and wealth-maximizing investors. Some work has been done on identifying different risk factors, but the APT does not indicate or provide guidance as to what the specific factors might be. This lack of factor identification has impeded the practical application of this methodology relative to the CAPM. In recent years, portfolio theory has been advanced by the introduction of a variety of new techniques using derivative securities such as futures and options. These developments have widened the range of tools available to optimize portfolio risk–return choices and extend the applicability of portfolio theory.

Postmodernism and Public Policy

Thomas J. Catlaw

Margaret Stout

School of Public Affairs, Arizona State University, Phoenix, Arizona, U.S.A.

INTRODUCTION

While somewhat limited to date, distinct elements of postmodern thought can be discerned in the contemporary literature analyzing both the study and the making of public policy. Considered here are the meaning of postmodernism, the historical condition referred to as postmodernity, broad categories of postmodern theory, and a discussion of ways in which postmodern ideas have influenced the contemporary understanding of the study and making of public policy. In conclusion, future trends and criticisms of postmodern approaches in public policy are discussed.

WHAT IS POSTMODERNISM?

Postmodernism is a complex, multifaceted term that has been used to describe a disparate and heterogeneous array of sometimes conflicting research projects; critical discourses; artistic, architectural and cultural movements; as well as a distinct historical epoch. The prefix “post” further complicates any straightforward accounting of the postmodern, since the word presupposes a stable, consensus understanding of *modernism*, itself a term of significant contestation and debate. Indeed, some scholars argue that postmodernism is a merely acceleration of modernist tendencies rather than a distinct theoretical or historical break. This complexity, however, can be understood by examining the term in two interconnected dimensions: 1) as a new historical period or different social formation and 2) as a specific body of philosophical critique and theory that calls into question basic assumptions of modernity, reason, and the enlightenment.

The Condition of Postmodernity

The term *postmodernity* is used to describe a new historical era or different social formation in which former traditions, values, and modes of understanding no longer seem to capture or describe our experience in the world.^[1] In this regard, the term shares an

affinity with other descriptors such as postindustrial, postideological, post-Fordist, late capitalist, and, more recently, global. It bears noting that postmodernity as a term is itself not new. It has been used by scholars and artists for more than a century to name the emergence of new social, cultural, and economic formations seen to be substantively distinct from “modernity.”^[2]

Be that as it may, by the 1960s, new modes of communication, technology, and information, as well as the explosion of wealth and consumerism, seemed to be producing a new, more chaotic, unstable experience of the world, one arguably in marked contrast to the rigidity of what Max Weber called the “iron cage” of bureaucratized modernity. This new sensibility emerged together with new cultural and artistic forms and movements that emphasized different values. For example, disintegration was elevated over integration, fragmentation and deconstruction over unification and totalization, chance over design, play over seriousness, difference and otherness over identity or sameness, disparate textuality over metanarrative, eclecticism over purity, populist over avant-garde, and surface over depth.^[3]

These reorientations in value from the modern to the postmodern also challenged social, political, and cultural hierarchies. This allowed many excluded groups, discourses, and knowledge to force their way into mainstream society. As a result, modernity’s relatively coherent context for collective, authoritative meaning and identity—a stability purchased in no small part through the systematic and deliberate exclusion or marginalization of large groups of people from political, civic, and economic life—grew destabilized and people began to seek stability in smaller communities of meaning to compensate for this “thinning” of macroreality.^[4,5] While these communities can be affirmative and inclusive, they sometimes assume exclusionary forms quite at odds with the general postmodern embrace of otherness and difference, as in religious fundamentalist enclaves.

Complex changes in the political economy were also taking place, which were both producing and products of these social and cultural changes. In the industrialized parts of North America, Europe, and the Pacific

Rim, economies experienced a radical restructuring from centralized mass production to a more flexible, mobile form of capitalism that was far less accommodating to labor. In industrialized countries, new forms of communication and information technology increased focus on the production of services and cultural, informational, and symbolic commodities, shifting manufacturing to developing nations. Keynesian approaches to macroeconomic regulation of the business cycle as well as the social benefits and securities of the welfare state were gradually abandoned or seen as ineffectual, and a more limited role for government in the governing of society was advocated.

Some argued that these conditions were leading to the decline of the nation-state as the dominant form of political and social organization. While this is a debatable proposition, it remains the case that as societies fragmented culturally and economically, so did the work of governing. Several factors contributed to this. The late 1960s and early 1970s witnessed: 1) legal changes that made participation in regulatory and administrative proceedings easier for citizen groups; 2) growing demands from both the political Left and Right for local, community control; 3) an explosion in grassroots advocacy groups that grew out of the new social movements (e.g., environmentalism and women's and civil rights); and 4) in conjunction with the fragmentation and struggle for inclusion of marginalized groups noted above, the increasing pluralization of values, cultures, traditions, and styles of life.^[6]

As a result, traditional modes of policy making, so-called "iron triangles," were displaced by broader-based policy networks, as ever greater numbers of actors and points of view became involved in the formulation and execution of public policies. Moreover, fiscal uncertainty, the perceived failure of ambitious social engineering programs, and growing anti-governmental feelings and political conservatism precipitated the search for new decentralizing techniques of governing, such as privatization, contracting out, and coproduction. These reform efforts brought more actors and institutions into the governance process and reduced the visible size and scope of central governments.

Some have also contended that in these fragmented, media-saturated conditions, politics has become a game of "symbol manipulation" rather than a democratic dialogue about substantive issues.^[5] A related concern is expressed by those who feel that the policy-making process has become inappropriately dominated by interest group competition. As a result, many argue that elites rather than the broader public shape public policy through covert and manipulative activities, which restrict democratic participation and produce results that are neither in the interest of the society as a whole nor the specific targets of public policies.

Postmodern Theory

The second dimension of postmodernism is associated with a stream of radical critique that emerged from France in the 1960s. Following the Second World War, existentialism, Marxism, critical theory, phenomenology, and hermeneutics were the dominant intellectual tendencies. But by the 1960s, these ideas were challenged by linguistically based social scientific and philosophical inquiry that drew from the structuralist linguistics of Ferdinand de Saussure (1857–1913) and his critics that followed. The shift from structuralism to poststructuralism in philosophy is often used to mark the theoretical emergence of the constellation of ideas comprising "postmodern theory." These "post-" theories argue that structuralism had not gone far enough in severing connections with the assumptions of modernity, humanism, and theoreticism. Major postmodern theorists include Jean Baudrillard, Jacques Derrida (1930–2004), Michel Foucault (1926–1984), Jacques Lacan (1901–1981), and Jean-Francois Lyotard (1924–1998). American pragmatist philosophy also has been an important influence on the development of postmodern thought (e.g., Richard Rorty (1931–2007)).

While there is considerable variation among postmodern theorists and their followers, three core components in postmodern theory can be identified.^[7] First, the *critique of the human subject* calls into question the notion of an autonomous, coherent, and substantial self. In postmodernism, the self becomes an effect of power (e.g., Foucault) or discourse. It is exploded into a multiplicity of partial identifications or intensities without a fixed center for reflection, critique, or action. Second, the *critique of historicism* rejects the teleological view of history, the idea that there is an underlying meaning, pattern, or trajectory to historical events. Related to this antihistoricism is the well-known characterization of postmodernism as rejecting all *metanarratives*, or the possibility of a single, overarching narrative that can interpret all objects and phenomena. In this regard, postmodern theory prefers local micronarratives. Third, the *critique of meaning* rejects the postulate that words refer to substantial things and that we can ever have an unmediated access to reality. Instead, the world and our experience of self are socially constructed by and through language. This general stance of *antirepresentationalism* is perhaps the single most important notion in postmodern thought, arguing that language does not "mirror" reality because there is not a given object "out there" to be re-presented. Rather, objects are produced by and apprehended through language. Politically, for many postmodernists, this critique of epistemology is also linked to critique of political representation and a preference for participatory

practices. This can be a position somewhat at odds with the critique of the subject.

AFFIRMATIVE AND SKEPTICAL POSTMODERNISTS IN SOCIAL SCIENCE

Emerging primarily from the tradition of continental philosophy, the postmodern critiques share much with postpositive philosophy of science, which is associated with the analytic philosophical tradition. Like postmodern theory, postpositivism rejects the core tenets of conventional, positivist science, i.e., realist ontology, objectivist epistemology, and a strict separation of facts and values. While there is controversy concerning the difference between postpositivism and postmodernism, some postpositivists argue that the postmodern position critique of meaning and its insistence that all experience is constituted by language are too extreme. There also can be political differences. Reflecting the influence of Marxism and philosopher Friedrich Nietzsche, postmodernists frequently advance a more radical critique of existing political and social institutions; postpositivists often retain a commitment to and faith in liberal institutions. Others choose to avoid the term postmodern altogether, believing that it has acquired a negative, even derogatory, connotation.

Even among postmodernists, however, there is variation that challenges any neat categorization. Rosenau draws a distinction between “affirmative postmodernists” and “skeptical postmodernists.”^[8] Whereas skeptics may reject the idea of objectivity and possibility for discriminating among truth claims altogether, affirmative postmodernists accept that knowledge and experience are linguistically mediated and socially constructed but argue that we still can know something about the world. They seek a “philosophical and ontological intellectual practice that is non-dogmatic, tentative, and non-ideological” (on page 16 of Ref.^[8]) and adopt a reflexive, flexible attitude with regard to our concepts and constructions.^[9] Affirmatives contend that objectivity can be redefined as intersubjective agreement. This is a *consensus theory of truth* that stands in contrast to the law-like explanatory reasoning designed for prediction and control that characterizes positivism.

POSTMODERNISM IN PUBLIC POLICY

In general, the reception and application of postmodern ideas in the field of public policy research and analysis can be characterized as an affirmative postmodernism: With an acceptance of social construction and intersubjective meaning, collective understanding,

decision, and action are considered possible. Each of the postmodern critiques (i.e., of the human subject, historicism, and meaning) has made an impact on the study and making of public policy. For example, to confront the effects of power and language on the human subject, critical and interpretive approaches to policy studies and participative practices are advanced. To avoid historicism and metanarratives, local and subjective interpretations of meaning must be accommodated in both studies and participative policy analysis. To address the critique of meaning, multiple forms of knowledge, without privileging any type or social actor, are advocated in the policy process. Furthermore, challenges to representation as not only a form of meaning but also a political institution demand a more directly democratic and discursive practice in the making of policy.

Specifically, dimensions of postmodern theory’s critique as well as the conditions of postmodernity are evident in contemporary policy scholarship in three principal areas: 1) the critique of rationality in policy making; 2) postpositive approaches to policy studies (sometimes calls “postempirical”); and 3) the call for a more participatory approach to policy making. Together, the rational approach to policy making and the positivist approach to its study have been labeled the “rationality project” by Stone.^[10]

Critique of the Rational Approach to Policy Making

Postmodern critique calls into question the bases of the rationalist approach to policy formulation. As an idealized prescription for policy making, the rational approach assumes that policy develops according to an orderly five-stage process. First, objectives are identified; second, alternative courses of action are postulated for reaching the object; third, the consequences of each alternative are predicted; fourth, the consequences are evaluated; and fifth, the alternative that maximizes benefits and minimizes costs is selected. This model of reasoning assumes that there is a single vantage point from which judgments about the good can be made. It also assumes a specific conception of society, namely the market, which is viewed as “a collection of autonomous, rational decision makers who have no community life” (on page 9 of Ref.^[10]).

Both the empirical veracity and the prescriptive ideal of the model have been challenged. In regard to the former, while Kingdon should not be labeled as a postmodernist, his work shows that the process by which policy is made hardly conforms to the stages of the rational model.^[11] Kingdon analyzes the complex “primeval soup” (on page 19), in which experts, citizens, politicians, and administrators interact and

shape the way in which issues get on the agenda. This political context shapes the identification and selection of alternatives. Kingdon argues that there are largely independent streams that flow through the process—a policy stream, a problem stream, and politics stream. There is no single, overarching way to describe how these streams come together or, as Kingdon writes, how a “policy window” opens.

More clearly aligned with postmodern theory, other scholars challenge the normative prescription of economic rationality from various normative perspectives. Stone argues that the rationality project aims to purge society of political conflict. In dismissing politics, the rational approach to policy making misses the fact that policy problems and objectives are not given but are constructed through specific categories of language and schemas of classification. As such, policy problems have multiple, conflicting perspectives and interpretations and are infused with paradox, difference, and conflict. For example, Stone shows how policy can be changed by redefining the category through which people understand causality. Are people on welfare because they are inherently lazy or have been made so by the welfare system? Or are they impoverished because of pervasive disenfranchisement as marginalized groups? The two causal stories lead to very different public policies. To govern democratically in these conditions, Miller, perhaps unique in working through the full implications of the postmodern critique for public policy, argues that we need institutions and public policies that ensure against “the domination of any one truth, any singular idea, or any unifying system of social practice” (on page 99 of Ref.^[12]).

All these perspectives challenge the traditional authority of the policy expert. From this perspective, democratic governance is harmed by the usurpation of political deliberative processes by technical experts and decision-making processes that are not broadly inclusive.^[10] This changes both the nature of policy research and the policy making.

Postpositive Policy Studies

Miller argues that “we should see policy research as stemming from the necessity to form common understandings with others who are interested in the same vexations and the same social problems” (on page 67 of Ref.^[12]). There cannot, therefore, be simply one expert view or perspective that captures the complexity of a social problem. Rather, there are many possibilities for framing inquiry. Extending these concerns to policy studies, the postpositive approach to public policy adopts a general ethos of methodological pluralism, combining empirical and normative inquiry without privileging one particular form of rationality,

quantitative over qualitative methods or expert over citizen roles. This accommodates a “reconstructed methodology” that produces a more well-rounded scientific knowledge.^[13]

Consistent with the postmodern awareness that the world is socially constructed, meaning (including both fact and value) is made through language, actions, and cultural objects, including theory. Thus, all research, including policy analysis, is a process of interpreting facts and values, both of which are mediated by theory, culture, and language. When the focus is on culture and language, this approach to policy studies is often referred to as an argumentative, rhetorical, communicative, or linguistic turn. When the focus is on theory, it is asserted that theories, methods, and rules guide interpretation, explanation, prediction, and evaluation.^[14] Therefore, theory, fact, and value cannot be segregated within policy discourses. This further challenges the position of the expert.

The common denominator among these approaches is that they all take an *interpretive* view that “the creation, communication, and understanding of meaning require attention” (on page 111 of Ref.^[15]). These policy scholars focus attention on the way in which people use linguistic categories, symbols, and frames to interpret the world and seek to understand how these interpretations impact the issues considered, the policy tools preferred, and the legitimacy of the outcomes sought. Assuming goals of understanding rather than prediction and intersubjective agreement rather than objectivity, policy analysis and inquiry become an ongoing process of interpretation or critique that includes multiple forms of knowledge and models of reasoning, a process that extends to policy research itself. Scholars and policy experts must be reflexive and aware of how their own frames and theories affect their work.

Participatory Policy Analysis

Postmodern conditions can be cause for deep concern insofar as they seem to replace substantive democratic politics with empty symbolism and elite manipulation. However, for some policy scholars, the fragmented, perspectival, and uncertain nature of the “postmodernized” policy process offers the conditions for the rebirth of a robust, participatory democratic politics.^[16] Postmodern theory also points in this direction.

Postmodernized policy studies seek to answer the question “Why?” by understanding from the perspective of the subjects of inquiry. When applied to practice, then, one of the most effective ways to understand the perspectives of those impacted by the issue of concern is to include them directly in the policy-making process. Rather than enforcing sometimes arbitrary

divisions between experts, politicians, and citizens, boundaries are blurred and all policy actors become “policy analysts” together. Indeed, many scholars call for direct participation in the policy-making process as the way to ensure the best interpretive outcomes.^[17–19] This implies an approach to citizenship, governance, and public policy that is non-hierarchical and egalitarian in nature. As such, some view it as a challenge to the “broken” institutions of representative government, replacing them with deliberative and discursive forms of democracy.

Postmodern theoretical critique also points in this participatory direction. The critique of the subject suggests that people’s values and interests are not static, as assumed by the rationalist approach to policy making. Instead, through dialogue and deliberation preferences can change. Furthermore, our own understandings of our true interests may not be transparent due to the effects of social power. To avoid metanarratives, local interpretations of meaning must inform the determination of the problem and alternatives for policy action. Expertise has an important role to play, but it cannot be the only narrative that informs policy. To address the critique of meaning, policy making must make use of multiple forms of knowledge without privileging any type of social actor, and challenges to representation demand a more directly democratic and discursive practice in the making of policy.

In sum, scholars recommend participative practice to overcome the problems identified by postmodern theory as well as the conditions of postmodernity.

CRITIQUES OF POSTMODERNISM IN PUBLIC POLICY

Postmodern approaches to the study and making of public policy are not without their critics. Some suggest that postmodernism is nothing more than an extension of critiques that have been ongoing in the philosophy of science as well as public policy for some time and, as such, that postmodern theory attacks a highly caricatured image of science. For example, elite theory has suggested concerns about inclusion, authority, legitimacy, and justice in the making of democratic public policy from its beginning. However, postmodern theories would argue that these critiques are still attached to the underlying positivist philosophy and explanatory mode of research that they purport to critique and that the rational model remains the prescriptive ideal for policy making. In this connection, scholars also challenge postmodern public policy studies, analysis, and evaluation based on an epistemological and methodological resistance to non-positivist science.

A related critique is that participative and communicative practices do not ensure that valuable

scientific and technical knowledge will be considered, thus failing to produce the best policy outcomes. Another critique is that even when practical direction is offered, it fails to meet its democratic objectives. For example, a common complaint about any type of participative or discursive practice is that it is too time consuming and lengthy for “real-world” policy-making and is thus cut short or trivialized. Both of these barriers may be due to the fact that our society is simply not socialized toward political participation. Finally, some postmodernists critique the very ideas of policy and reason.^[20] For these theorists, postmodern public policy does not go far enough.

CONCLUSION

Just as it has taken several decades for the limitations of positivism to become evident, the jury remains out on what the long-term impact of postmodern policy research and applied methods will be on social science and society. However, it seems likely that so long as the conditions of postmodernity continue, postmodern theory will continue to play an important role in shaping how we understand and practice the study and making of public policy.

Postpositivist Perspectives in Policy Analysis

Göktuğ Morçöl

School of Public Affairs, Pennsylvania State University at Harrisburg,
Middletown, Pennsylvania, U.S.A.

INTRODUCTION

Postpositivism is a group of philosophical perspectives that are critical of positivist assumptions and methods. In philosophy and social theory, they emerged in the early- to mid-20th century and, in the policy analysis literature, in the 1980s.

Both positivism and postpositivism are vaguely defined terms. *Positivism* is sometimes used interchangeably with *empiricism*, *behaviorism*, and *naturalism*. Two philosophical movements called themselves positivist: the 19th century French sociologist August Comte coined the term and the Vienna Circle of philosophers of the early 20th century (Rudolf Carnap, Otto Neurath, Moritz Schlick, and others) adopted the name *logical positivist* (or *logical empiricist*). Some critical theorists of the Frankfurt School define positivism more broadly and label Karl Popper and the later writings of Karl Marx positivist.

The philosophical predecessors of postpositivism are the hermeneutic theories of the 19th and 20th centuries. The critiques of positivism by Karl Popper, the critical theorists of the Frankfurt School, and Thomas Kuhn established postpositivism as a philosophical perspective. Postpositivist philosophical arguments are reflected in the policy analysis and evaluation literature in five theory streams: the contextuality and presupposition theories, problem structuring and issue framing theories, the methodological critique, critical hermeneutics, and participatory policy analysis theories.^[1]

Weimer^[2] and others question the relevancy of postpositivist arguments to policy analysis, because, they think, most of policy-analytic theory and practice is not even positivistic. On the other hand, postpositivists such as Fischer^[3] argue that the failures of the positivist policy analytic theory and practice in the 1960s and 1970s led to the surge of the postpositivist critique in the 1980s and that positivism survived despite the critique because it still is professionally, organizationally, and politically expedient. Morçöl^[4] found in a survey that positivistic assumptions are prevalent at varying degrees among policy professionals.

ASSUMPTIONS OF POSITIVISM

Although the exact roots and scope of positivism are debatable, a set of assumptions can be identified as

its core: a realist and deterministic ontology, an objectivist epistemology, and the belief in a fact-value distinction. Positivists use reductionist and analytical methods and believe in the primacy and superiority of quantitative methods.

Realism is the belief that the world exists independently of and prior to the knowledge of a knowing subject. The logical positivist of the early 20th century as well as August Comte and Karl Marx were realists. Positivist policy analysts assume that policy problems exist independently and can be identified and solved objectively.

Positivists also believe that this independent reality is composed of discrete and precisely identifiable objects whose relations and motions are determined. The notion that the universe is deterministic has a long history; the most recent version, one that undergirds the modern science, was articulated by Francis Bacon, René Descartes, and, most importantly, Isaac Newton in the 17th century. In the Newtonian deterministic universe, the relations between past and future events are fixed. Therefore if a complete knowledge of the past is obtainable, then future events can be predicted precisely. The deterministic worldview is reflected in policy research in the use of the experimental method, which attempts to establish causalities between variables; the forecasting methods that use information about the past to predict future; and the theory and methods of long-term planning.

The notion that the objective knowledge of an independent reality can be acquired is a core positivist assumption. The validity of the acquired knowledge can be verified by checking it empirically against the reality itself. What follows is that factual knowledge—knowledge that has referents in reality and is verifiable—can, and should, be separated from values—inner, subjective preferences of individuals. Positivist policy analysis attempts to keep the respective realms of politics and analysis apart, on the basis of the belief that while values belong to politics, facts should be the domain of analysis.

APPLICATIONS OF POSITIVISM IN POLICY ANALYSIS

The reductionist/analytical methodology of positivism builds on the Newtonian scientific notion that objects are discrete and precisely identifiable and their

characteristics (weight, length, etc.) can be counted, measured, and compared with one another. It is also assumed that a quantitative form of knowledge is inherently and under all circumstances more scientific and objective than a qualitative form of knowledge. Such assumptions are reflected in the notion that quantitative pieces of information are “hard facts,” while qualitative ones are “soft,” and in the extensive use of statistics in policy research and policymaking.

The assumption underlying cost–benefit analysis is that costs and benefits of a program or project can be identified objectively and measured. The experimental method is considered the most scientific, primarily in psychology and policy and program evaluation, because it is assumed that experiments can isolate variables and establish deterministic relations (causalities) among them definitively.

POSTPOSITIVIST CRITIQUE IN PHILOSOPHY

The philosophical roots of postpositivism can be traced to hermeneutics. In the most general sense of the term, hermeneutics is the study of meanings in symbolic interactions (speech, written text, rituals, cultural artifacts, etc.). Hermeneutic philosophers follow Wilhelm Dilthey's (1833–1911) distinction between the natural and social sciences: while the natural sciences aim to develop causal explanations of “outer” events, the social sciences are concerned about an “inner” understanding of meaningful human actions; therefore they should use different methods of inquiry.

Hermeneutic philosophers see social phenomena as texts to be interpreted. There are differences among hermeneutic philosophers as to whether there is a “true meaning” of a text, but the position of the German philosopher Hans-Georg Gadamer (1900–2002) is the most typical one. According to Gadamer, the meaning of a text is determined by an interaction between the intentions of the author and the interpretations of the reader, both of which are embedded in their respective particular historical contexts. It is not possible for a reader to know the entire historical context of the authorial intentions and hence the “true meaning” of his/her actions.

The Frankfurt School of critical theorists—Max Horkheimer (1895–1973), Theodor Adorno (1903–1969), Jürgen Habermas (1929–), and others—synthesized hermeneutics with Hegelian philosophy and Marxism. Habermas affirms the hermeneutic distinction between the natural and social sciences and argues that if we attempt to use the methods of the natural sciences in the social sciences, we turn the latter into “social technologies.” This instrumentalist use of knowledge in the social sciences cannot be objective; in fact, it is used to perpetuate the social structures

of domination. Habermas sees the task of the critical theory as to contribute to an emancipatory knowledge of society.^[5]

In his critique of logical positivism, Karl Popper (1902–1994) aimed to show that scientific knowledge could not be positively verified and offered a *falsificationist* alternative: if a hypothesis has not been falsified, it can be accepted only as a tentative truth. Because Popper shared some of the core convictions of logical positivists (e.g., that science offers the most reliable form of knowledge because it is open to empirical testing), the critical theorists Adorno and Habermas characterized his work as an “internal critique” of positivism.^[5] However, his demonstration of its weaknesses opened the door to a deeper critique of positivism.

Thomas Kuhn (1922–1996) offered a sweeping critique of the positivist understanding of science in his book *The Structure of Scientific Revolutions* (1962). He argued that scientists work in *paradigms*, belief systems that are “incommensurable.” Paradigms are shaped in social and historical contexts. They determine which methods to be used and how the “facts” are “discovered.” Therefore the positivist principle of fact-value dichotomy and hence its objectivist epistemology are not sustainable.

POSTPOSITIVISM IN POLICY ANALYSIS

Fischer^[3] points out that the social crises and the failures of governmental policies in the United States in the 1960s and 1970s forced a rethinking of the assumptions and methods of the social sciences; those social scientists who were concerned about the role the social sciences played in the ideological manipulation of the poor and disadvantaged groups in the society began to formulate alternatives to positivist, instrumentalist, technocratic, and undemocratic forms of policy analysis. In the following decades, five theory streams emerged that are critical of positivism in general or some aspects of it: contextuality and presupposition theories, problem structuring and issue framing theories, the methodological critique, critical hermeneutics, and participatory policy analysis theories.

The *contextuality and presupposition theorists*, such as M.E. Hawkesworth, make the case that the theory and practice of policy analysis are predominantly positivistic.^[6] They also argue that policy-analytic knowledge is presupposed—mediated by analysts' preconceived notions and values—and formed in historical, cultural, and political contexts. With such assertions, this group of theorists provided the general justification for a postpositivist critique of the mainstream policy analysis.

The *problem structuring and issue framing theories* also recognize the contextuality of policy-analytic

knowledge and focus particularly on the significance of the way policy problems are structured. William Dunn points out that policy problems are typically ill-structured because they are socially constructed, dynamic, and interdependent.^[7] He argues for a conscious, systematic, and continual structuring and restructuring of problems throughout the policy analytic process. Schön and Rein^[8] point out that participants in policy processes construct problems through their mental frames in which facts, values, theories, and interests are intertwined. Schön and Rein call for a *frame-critical policy analysis*, in which the role of the analyst would be to understand frame conflicts and help participants reframe to reach policy resolutions.

In their joint and individual works, the late Donald Campbell (1917–1996) and Thomas Cook articulated a *methodological critique* of positivist methods. Campbell argued that positivists failed to recognize the equivocal and ambiguous nature of experimental research and the historical indexicality of the variables used. Cook and Campbell^[9] offered quasi-experiments as an alternative to remedy the shortcomings of the experimental method. Cook^[10] recognized the inability of positivistic methods to generate objective and precise knowledge by arguing for a *critical multiplist* methodology that would be anchored in realist ontology, but it would also use multiple methods, multivariate causal models, and multiple theoretical frameworks.

Hajer^[11] and Fischer^[3,12] represent the *critical hermeneutic* perspective in postpositivism. In his discourse analyses, Hajer shows that knowledge and power are articulated through discourse and human actors engage in struggles for discursive hegemony in policy processes. The influence of Habermas' critical theory can be seen most clearly in Fischer's works. He is critical of the instrumentalist and technocratic uses of the policy-analytic knowledge by analysts and policymakers because such uses support undemocratic practices. He proposes a participatory policymaking process, with the involvement of multiplicity of actors and interests. He emphasizes that the policy-analytic knowledge should also be transformational and emancipatory.

Participatory policy analysis has other proponents as well, although they do not necessarily come from a critical hermeneutic perspective. Kelly and Maynard-Moody,^[13] for example, suggest that policy stakeholders should be involved in framing research questions and selecting the methods of inquiry. The task of an analyst should be to facilitate rational deliberations, help policymakers and citizens understand the limitations of their perspectives, and synthesize multiple perspectives. Since the early 1990s, there is a growing literature on the use of participatory methods in the policy process—stakeholder analysis, Q-methodology, citizen panels, Internet-facilitated

dialogue and analysis, and the like—in the leading journals of the field, such as *Policy Studies Journal*, *Policy Studies Review*, and the *Journal of Policy Analysis and Management*.

CONCLUSION

Postpositivists are not unified in their critique of or alternatives to positivism, but, in general, they emphasize the historical, social, and political contextuality of the policy-analytic knowledge, argue and demonstrate that facts and values are intertwined in the policy process, call for an understanding of the discursive nature of policymaking, expose the power relations in the policy process, and call for a more democratic and participatory policy process in which analysts would play a facilitative role.

There is another theory stream that shares some of the assumptions and aspirations of postpositivism: postmodernism/poststructuralism. *Postmodernist/poststructuralist* theories also have their roots in hermeneutics. Because of this commonality in philosophical roots and the vagueness in the uses of the terms postpositivism and postmodernism/poststructuralism, it is not easy to draw clear demarcations between the two. Fischer offers a distinction: while postpositivists see a chance of establishing a common basis for a valid discourse, truthfulness of interpretations, among different perspectives, postmodernists do not.^[3]

Postmodernists/poststructuralists deny any “epistemological privilege” to any interpretation over another. In the works of Ferdinand De Saussure and Jacques Derrida, language is defined as a closed, self-referential system. As such, language does not have any reference to an “external reality”; therefore there is no basis for establishing truthfulness in knowledge. Poststructuralists use the method of deconstruction to demystify texts by revealing the arbitrary hierarchies and power bases in the seemingly rational and scientific discourses. They aim to delegitimize the socially constructed bases of authority and level the playing field for alternative, underprivileged discourses.

Schram's^[14,15] works are examples of the postmodernist/poststructuralist approach in policy studies. He aims to expose the power relations embedded in the public policy process. Schram denies any “epistemological privilege” to social scientists and policy analysts in the analytical process and argues that the policy analysis practice should be abandoned and policy analysts and academics should join the political struggle for social change.

Postpositivism and postmodernism/poststructuralism are open-ended projects. What direction each will take and whether they will merge into a larger stream remain to be seen.

Practical Organization Theory

Gerald T. Gabris

Division of Public Administration, Northern Illinois University, DeKalb, Illinois, U.S.A.

INTRODUCTION

For many public managers, the relevant question is not “why does something work,” but more simply, “what does work? For practitioners of public administration, the quest has always been toward the practical, the workable, and the doable. Defining and explaining what “practical organization theory” is all about serves as the focus for this article. Practical theory (PT) eschews simple definition. Yet for the purposes of this discussion, PT will be defined as follows. Practical organization theory provides simplified solutions to common issues and problems managers face in public organizations based on more complex and abstract theory. The simplification of theory provides managers with ready answers to practical problems. Simplification, however, can incur a price. Practical models often have somewhat limited application, they may generate contradictory advice, and they may oversimplify situations. Nonetheless, practicing managers are often willing to accept these risks given the direct applicability of PT. This article will first describe the methods and vehicles PT utilizes to become user-friendly to managers, followed by a select description of PT examples reflecting these methodologies. This article will conclude with a brief consideration of potential PT pitfalls.

VEHICLES FOR MAKING PRACTICAL THEORY USER-FRIENDLY

At the outset, it should be stated that PT encompasses such a broad range of concepts, models, and remedies that it would be impossible to categorize all these in a short descriptive essay. Thus, our purpose focuses on the common characteristics of PT rather than serving as a source for all PT possibilities. Central to this task involves identifying the “methodology” or medium through which PT is communicated and explained to practitioners, so they can use it quickly and expeditiously. With the risk of omitting some PT methods, the list below provides perspective:

- The use of principles or platitudes.
- The use of acronyms.
- The use of simple diagrams, charts, or figures.

- The use of metaphor and how-to-do-it books.
- The use of stories and anecdotes.

Although other media for PT exist, the above list captures the lions share. Let us review each of these briefly to understand how they work.

PRINCIPLES OR PLATITUDES

Principles normally involve simple statements that tend to proselytize some organizational or managerial “wisdom.” Examples might include the “Peter Principle” or notion that everyone rises to a level of their incompetence.^[1] Other off-cited principles include unity of command, span of control, and the exception principle.^[2] These ideas can be helpful to public managers. There should be only one boss, hence, avoid project management models. Limit the number of subordinates that any one supervisor is responsible for about six, and only bring exceptions to managers for decisions. Otherwise, follow standard operating procedures. These principles can be used practically to structure an organization, to firm up chain-of-command, to determine the number of managerial staff needed, and to solidify work routines. No wonder principles and platitudes are so popular among public managers, they tell them what to do and what works without a messy theoretical explanation.

ACRONYMS

Acronyms are merely words formed from the first letter or groups of letters from larger, more complicated phrases. One of the most renowned acronyms in management is POSDCORB.^[2] POSDCORB stands for “planning, organizing, staffing, directing, coordinating, reporting, and budgeting.” By using an acronym, a manager has a nifty memory device that enables one to remember their responsibilities without having to memorize each one individually. What constitutes my job, well, POSDCORB. Acronyms simplify. An acronym common to human resources managers is “KSAs.” This informs HR staff that in interviewing people for jobs they need to assess the applicants “knowledge, skills, and abilities.”

DIAGRAMS, CHARTS, OR TABLES

This is a somewhat broader category that is relatively self-descriptive. Again, PT diagrams or charts strive to simplify a complex idea or theory to make them more user-friendly to managers. An example of this would be Robert T. Golembiewski's simplified bureaucratic organization chart. This is replicated in Fig. 1.^[3]

This simplified organization chart applies to any public bureaucratic organization. There is a general manager (GMabc), specialized supervisors (S1, S2, and S3), and specialized employees (little a, b, and c). From this model, we can deduce much about bureaucratic behavior, including communications, upward mobility, chain of command, task responsibility, and interunit competition. The model cuts to the quick regarding bureaucratic behavior, thus facilitating a useful, user-friendly mechanism that public managers can understand quickly. Another figure or diagram simplifying complex ideas can be related in Fig. 2, which depicts the characteristics of degenerative and regenerative interpersonal interaction patterns.^[3]

In Fig. 2, we learn that low trust associates with low openness (communications), higher risk, and low owning (taking a stand for one's values). Put another way, a problem in one area, say trust between coworkers, usually precipitates a ripple effect that influences positively or negatively, other interpersonal variables. Thus, the diagram serves as a simple diagnostic mechanism enabling managers to clearly see how a downturn in one area of interpersonal relations may red flag problems in other areas.

METAPHORS AND HOW TO DO IT BOOKS

Practical theory can be expressed in simple metaphors and analogies that provide managers with an instant understanding of a practical concept. One good example of this is the short book by Blanchard and Johnson entitled, *The One Minute Manager*.^[4] Essentially, this book is a short compendium of multiple management principles conveyed in story form. The advice offered reflects practical managerial common

Fig. 1 The bureaucratic model.

Degenerative			Regenerative		
Status		Characteristic		Status	
Low	-	TRUST	-	High	
Low	-	OPENNESS	-	High	
High	-	RISK	-	Low	
Low	-	OWNING	-	High	

Fig. 2 Degenerative and regenerative interpersonal interaction patterns.

sense such as taking a minute to form one's goals, giving feedback, praising employees, and explaining decisions to subordinates. Most of these things take only a short time but produce big results, hence, the metaphor, "one minute manager."

A somewhat similar approach is utilized in a highly useful book by Robert Bramson entitled, *Coping with Difficult People*.^[5] This can be properly termed a "how-to-do-it" manual that utilizes metaphors to explain difficult employee behavior. Bramson utilizes such colorful metaphors as "Sherman tanks, snipers, and exploders" to describe hostile, aggressive behavior. Conversely, "clams" are persons who use unresponsiveness as a defensive routine. By explaining behavior in these colorful terms, the author paints graphic pictures in one's mind of things people can relate to, such as tanks, bombs, snipers, and clams. Then, by giving relatively simple quick fixes to these problems, managers acquire practical solutions for dealing with difficult people, without having to know very much about human relations theory or behavioral psychology.

Another aspect of PT involves the fact that it often incorporates several media to relay its messages. A how-to-do-it book may utilize principles, metaphors, acronyms, stories, and anecdotes. Several contemporary examples of this genre of literature include:

- *Reengineering the Corporation*.^[6]
- *Reinventing Government*.^[7]
- *Principled Centered Leadership*.^[8]

The list could obviously go on at length given the demand from managers for practical, useful, organizational advice. Again, the goal is to relate things to managers in ways they can comprehend and apply to specific situations and needs.

STORIES AND ANECDOTES

A final example of a PT medium relates to stories and anecdotes. Everyone likes a good story, including

managers. Stories have a way of grabbing one's attention toward an interesting topic that formal theory cannot match. Stories teach lessons, and one can then take these lessons and apply them to one's own situation. An example of a PT story is the "Abilene Paradox" developed by Jerry Harvey.^[9]

In Harvey's account, his family was relaxing on a Sunday afternoon in a small Texas town wondering what to do. It was hot, approaching 104 degrees. Someone mentioned going to Abilene. Now, several did not really want to go, but felt other family members wanted to. In actuality, no one really wanted to go, but once the idea was set in motion, all agreed to go, thinking this was the group consensus. After having a miserable time on the drive home, everyone confessed they did not really want to go in the first place but went along thinking this was what everyone else wanted to do.

The lesson of the story is this. We often engage in unhealthy agreement. We may not wish to pursue a course of action but go along, thinking this is what our coworkers want to do. They may go along thinking this is what we want. Hence, there is a "crises of agreement." The Abilene paradox is just one example of stories that teach important practical lessons. Many of the how-to-do-it books utilize this technique as well. Extremely popular management books such as *In Search of Excellence*^[10] and *Reinventing Government*^[7] are mainly comprised of short stories and anecdotes about management techniques and practices that have proven successful. These books touch on theory but rely on stories and anecdotes as their primary teaching vehicle.

So, given the value of PT for practicing managers, what could be defective with this strategy, what are its limits and potential drawbacks? We now address this issue.

LIMITS AND PITFALLS OF PRACTICAL ORGANIZATION THEORY

The saying goes, "there is a cloud with every silver lining." So it is with PT. Because the utility of PT often stems from its simplification of complex theory, it may not effectively deal with the many nuances of organizational behavior required to fully understand some issue or problem. Take, for example, span of control and unity of command. By suggesting that span of control be limited to six subordinates, the question quickly arises as to whether this advice is useful for many special situations. If tasks are simple or if employees have considerable knowledge about their work, they may need little direct supervision. Here, a much broader span of control may be effective.

Similarly, some projects may necessitate employees working together from different divisions, thus warranting multiple project supervisors. Broad principles have difficulty with nuance and tend to oversimplify.

Noted scholar Herbert Simon points out another pitfall of practical theory, namely, it frequently takes on a "proverbial" quality that leads to internal contradictions between principles.^[11] For example, unity of command if followed to the letter, denies the possibility of interunit cooperation for problem solving and creates difficulties with span of control. By striving to maximize one principle, this can lead to contradictions in other principles. The platitudes, appealing to common sense, may tell us to do different things simultaneously. Hence, which should we follow?

Practical organization theory may also oversimplify and convey a false sense of knowledge to managers that they then act upon. This could lead to serious problems. For example, some managers may learn how to handle certain problems in "one minute." Others may feel they now have a handle on how to work with certain kinds of difficult employees who display hostile aggressive behavior. Yet, the range of knowledge these condensed and simplified theories provide may be insufficient for dealing with unique issues, special cases, or deeper problems. Managers, in this sense, may overestimate their ability to handle situations, thus leading to worse outcomes.

CONCLUSION

As with any type of knowledge or technique, trade-offs exist. Practical theory provides many useful and easy to comprehend approaches to problem solving that are attractive to public managers. These techniques, principles, and simplified theories provide quick and ready answers to a large bevy of issues confronting managers on a day-to-day basis. They are, therefore, attractive, for they seem to provide a magic bullet, a quick fix, or a clear answer.

Yet, as we have also suggested, they may incur some risks. Developing skill for telling the difference between useful practical theory and faddish hoopla requires practice and experience. Fundamentally, managers must learn to balance the benefits against the potential losses PT may involve. Perhaps this becomes the key issue, because as long as we have managers who continually face streams of organizational issues on a day-to-day basis, we will have practical theory. Practical theory provides managers with an answer to the question "what works." Given the stress and constraints placed on the time of most public managers, such answers become "manna" from heaven.

Pragmatism and Public Administration

Keith F. Snider

Naval Postgraduate School, Monterey, California, U.S.A.

INTRODUCTION

Pragmatism has two meanings; first, it is a turn-of-the-twentieth century movement in American philosophy, and second, it is an attitude of expediency and practicality. The contributions to and influences on public administration by the former are tenuous and ill-defined, considering the field's generally atheoretical orientation. The latter, on the other hand, is clearly evident in public administration's perennial concerns with the practical day-to-day concerns of governance.

PHILOSOPHICAL PRAGMATISM'S RISE AND FALL

Pragmatism arose in late nineteenth century philosophy as a way of thinking to mediate between two diverging trends. One trend—Darwinian, materialistic, scientific, probabilistic, and secular—portrayed humans as mere biological elements in apparently random universal processes. The other—idealistic, rationalistic, romantic, and religious—gave humans a central place in the universal scheme due to their powers of reason and their moral and religious sensibilities that infuse life with purpose and meaning. The first trend was criticized for ignoring moral considerations; the second was criticized for neglecting objective scientific facts. Pragmatism attempted to reconcile these two trends with the view that ideas dealing with the realm of values must have some practical consequence if they are to have any meaning.

The Early Pragmatists - Peirce, James, and Dewey

Charles S. Peirce (pronounced *purse*), generally recognized as pragmatism's founder, argued that ideas have clear meanings only in their operation—that is, in terms of their actions, effects, or consequences. For example, a rock is hard if it scratches something or soft if something scratches it. Apart from what is experienced as the practical consequences (the scratches) of the testing, the words “hard” and “soft” have no meaning. According to Peirce's “pragmatic maxim,” published in 1878, “Consider what effects, which might conceivably have practical bearings, we conceive the

object of our conception to have. Then, our conception of these effects is the whole of our conception of the object.”^[1]

Belief, according to Peirce, links thought and action. It is a settled state, arrived at on the basis of one's experiences of the effects or consequences of ideas. Experience is, however, always situational and contextual—any new or different sensing leads to the unsettled state of doubt. Inquiry or thought is the struggle to overcome doubt, thereby fixing belief at least provisionally. Peirce held the method of scientific inquiry to be the superior means for fixing belief. Because conceptions of things are based on sense experiences of their consequences, which should be observable and verifiable, belief may be fixed in a public sense to the extent that all observers can sense and agree upon the meaning of the consequences of ideas. Any concepts of knowledge, truth, or reality are thus socially constituted and always provisional.

Peirce's ideas received little notice, but they inspired both James and Dewey, whose work elevated pragmatism to prominence in the early twentieth century. William James, who first used the term “pragmatism” in 1898, appropriated Peirce's method for establishing meaning and extended it to a theory of truth. According to James, the test of any idea or belief is in the difference it makes in life, or as he put it, in its “cash-value.” For an idea to be true means that it must “work.”^[2]

John Dewey, whose pragmatism is also called instrumentalism or experimentalism, believed that the mind mediates between one's biological being and the various problematic situations it encounters. Thought is inspired by doubt or perplexity experienced in a particular situation. This unsettled state leads to deliberation and elaboration of competing hypotheses about how to resolve the situation. Thinking is not a quest for truth but rather an attempt to achieve adjustment with one's environment. Thought has an instrumental character in guiding action, thus ideas are plans of action or hypotheses, not representations of immutable truths or ends.^[3]

Philosophical Pragmatism's Integrative Character

The pragmatism of Peirce, James, and Dewey provided resolutions for philosophy's traditional ends-means,

fact-value, and thought-action dualisms. In place of metaphysical ends, pragmatism grounded value in human experience. People continually rearrange facts—the perceptions of experience—to form new ideas in response to their environment. The value of any idea is found in the extent to which that particular arrangement of facts serves to resolve some problematic situation. Values thus stem from and have meaning only in the facts of experience. Because actions may have value in resolving situations, values (or ends) are also inseparable from actions (or means). Finally, thinking is not isolated from experience but rather it continually reflects on experience to inform action to solve problems. Thought and action (or theory and practice) thus function in an integrated way.

Pragmatism and the Progressive Era

Pragmatism provided a philosophical basis for the progressive movement after the turn of the century. Pragmatism justified progressivism's unwillingness to accept the often appalling social and political conditions of the day as natural states of affairs and, accordingly, its vision of an active and expanded government. Legal, educational, economic, and political institutions that in the past had been used for purposes of power, greed, and oppression began to be viewed as instruments for change, amelioration, and progress.

Pragmatism's Decline

As James's and Dewey's influence spread, pragmatism took multiple and sometimes inconsistent forms depending on the background and interests of new proponents, which led to occasional conflicts and created confusion among observers. The extent of the diversity of approaches by 1908 is illustrated by one philosopher's attempt to clarify pragmatism's various interpretations in a series of essays titled *The Thirteen Pragmatisms*.^[4]

Perhaps more significant in pragmatism's decline was the dilution of its meaning as it spread beyond the discipline of philosophy into the broader public consciousness. James's catchy description of pragmatism as the "cash-value" in ideas had particularly popular appeal. Gradually, pragmatism in common usage came to mean simply doing what works or having an attitude of commonsensical practicality.

In the 1920s and 1930s, realism emerged to replace the Progressive Era's ambitious social optimism. The temper and spirit of the age changed dramatically in light of the horrors of the Great War and in the social and economic crises that followed. This new realism was exemplified in the writings of Reinhold Niebuhr,^[5]

who castigated public philosophers such as Dewey for their views of human and social perfectibility. Pragmatism had been so closely associated with progressivism that the disillusionment surrounding the failure of the movement could not fail to affect the philosophy.

In the 1930s, pragmatism came to be overshadowed by logical positivism. American philosophers, particularly at the University of Chicago, saw logical positivism as the cure for pragmatism's shortcomings, believing the two could be successfully merged. Others disagreed, noting irreconcilable differences.^[6] An especially significant incongruence was logical positivism's strict separation of facts and values, which held that value statements were meaningless because they could not be subject to empirical verification. This was of course contrary to pragmatism's view of facts and values as inseparable. Nonetheless, many were willing to sacrifice pragmatism's integrative character for logical positivism's rigor. This development heightened the general confusion and disillusionment with pragmatism, which faded as a significant force in philosophy for almost the next fifty years.

PRAGMATISM IN PUBLIC ADMINISTRATION

None of the pragmatist philosophers addressed public administration explicitly (though Dewey's *The Public and Its Problems*, published in 1927, is closest to the concerns of the field), and very few writers on public administration prior to the late twentieth century explicitly addressed pragmatism in any significant way.^[7] Pragmatism thus had little obvious or direct influence on the early field and its development. Serious treatment of pragmatism by public administration writers has only begun in the last thirty or so years.

The Founding Period

The usual account of American public administration's founding begins with the reform-minded writings and actions of Progressive Era men such as Frank Goodnow, Charles Beard, Frederick Cleveland, Luther Gulick, and Charles Merriam. This is the same general period when philosophical pragmatism emerged, but there is little evidence that it directly influenced these "early giants." Rather, they focused on the pressing problems of the day, showing little interest in philosophy. Science and its methods offered the best means for addressing and solving these problems, but politics had too often trumped science in the past. Public administrators thus had to be freed from political influences in order to employ their techniques and expertise. The proper orientation of the

emerging profession was toward value-neutral efficiency in administration.

While the founders' emphasis on problem-solving and science may seem at first blush to be coherent with philosophical pragmatism, their goal of value-neutrality actually opposed it. Pragmatism could not tolerate such a split between politics (the realm of ends or values) and administration (the realm of means and facts). That the founders thus reflected some aspects of pragmatism but not others helps explain occasional references to the field as "pragmatic."

The Founding to the Present—Traces of Pragmatism

The founders' initial value-neutrality has been described as leading in later years to an excessive emphasis on technique, rationality, and administrative expertise, which is blamed for public administration's theory-practice gap and its identity crisis. While this trend precluded serious consideration of philosophical pragmatism among most in the field, a few showed interest. Specifically, Mary Parker Follett relied heavily on William James in her essay "Community is a Process,"^[8] and John Gaus spoke approvingly of Dewey's *The Public and Its Problems*.^[9]

Apart from these few exceptions, pragmatism's influence on public administration can be characterized as either indirect or problematic. The managerial trend provides an illustration of pragmatism's indirect influence. With roots in Taylorism, this trend was reinforced by Leonard White's idea that management, not law, should provide public administration's foundation. It continued with organizational theorists such as Elton Mayo and Chester Barnard. Some aspects of the human relations movement seem based in pragmatism, for example, its contingency approaches and the instrumental roles assigned to managers and organizations in leading and caring for workers.^[10] None of the managerial theorists, however, worked directly from a basis in pragmatism. At most, their ideas were attenuated extensions of pragmatic philosophy into the arena of management; at the least, they simply reflected a few pragmatic characteristics.

An illustration of pragmatism's problematic influence on the field is seen in the policy sciences movement. Dewey has been linked as a contributor to this movement, which has origins in the 1920s among University of Chicago political science faculty such as Charles Merriam and Leonard White. This movement replaced the Progressive Era's faith in science and technology with a more constrained concern for cause-and-effect prediction and control through measurements of individual and social behavior. Yet, Dewey actually distanced himself from the movement, objecting to its

neglect of values in its empiricist behavioralism, and criticizing its inquiry as "superficial and comparatively trivial, no matter what its parade of technical skill."^[11]

Herbert Simon provides another illustration in his seminal 1947 work, *Administrative Behavior*. As a student in the Chicago political science department, Simon worked explicitly from logical positivism, which by that time had captured pragmatism, as discussed above. Simon was thus able to claim both James and Dewey as philosophical kinsmen while at the same time espousing a strict fact-value distinction. Pragmatism thus influenced Simon, but it was a corrupted and co-opted version from that of James and Dewey.

Other writers after World War II called into question public administration's separation from value-laden politics, as did Dwight Waldo in his 1948 book *The Administrative State*. Others, such as the contributors to the Inter-University Case Program,^[12] attempted to capture the rich complexity—including the politics—of administrative reality. While this turn agreed with pragmatism, none of these writers relied on it explicitly. Apart from these works, little else occurred with regard to pragmatism until the late twentieth century.

THE PRESENT REVIVAL OF PRAGMATISM

Since roughly 1970, two trends have contributed to a re-examination of pragmatism in public administration. The first is dissatisfaction among some scholars with the field's condition and a concomitant desire to rethink its foundations. This has led to historical analyses to discover or recover public administration's roots in pragmatism, as well as to reconstruction projects to reestablish the field in its ideas. The second is the influence of Richard Rorty's neopragmatism, which has contributed to a revival of interest in pragmatic thought.

The Road Not Taken—Jane Addams

The Progressive Era settlement movement, which had explicit philosophical connections to pragmatism, has recently been proposed as meriting a legitimate place in the history of public administration's founding.^[13] Jane Addams of Chicago's Hull House knew John Dewey from his frequent visits and relied explicitly on his and James's ideas in her writings. She saw the settlements as experimental approaches to some of the pressing social problems of the day. She also saw in them the potential for a more effective manifestation of democracy: participation by citizens in communities of inquiry. Addams thus embraced science and its methods, but, in contrast with public administration's

founders, she did not attempt to divorce science from questions of politics or value. This view of democracy as a participatory community of inquiry was also Dewey's central theme in *The Public and Its Problems*.

It of course remains to be seen whether this alternative account of public administration's founding in the explicit pragmatism of the settlement movement is accepted and, if so, what effect that acceptance may have on public administration's contemporary identity.

Richard Rorty and Neopragmatism

Rorty began to develop his particular form of pragmatism in the late 1970s, relying a great deal on the early pragmatist philosophers but also differing from them in important ways. Rorty's main departure from Peirce, James, and Dewey occurred in his arguments that they were insufficiently anti-foundational in their reliance on experience as a ground for meaning. That is, traditional pragmatism held that, because meanings of concepts are contingent, they must be grounded in experience. Rorty argued that this formulation made experience foundational when, in actuality, experience is simply a linguistic construction. Rorty has stated that it is better to ground pragmatism in language; hence his neopragmatism is sometimes called linguistic pragmatism. This turn sweeps away any and all foundations because language is a social construct. Progress thus obtains not from the scientific method, but rather through the creation of more appropriate vocabularies, languages, and ways of speaking.^[14]

His radical views and willingness to employ them in attacks on institutions and cherished beliefs have made Rorty a highly controversial writer. His radicalism notwithstanding, Rorty has had some influence in public administration, as some contemporary scholars see his linguistic pragmatism as holding promise as a central guiding mode of thought for the future.^[15]

CONCLUSIONS

Though attention to pragmatism among theorists and historians of public administration has increased in recent years, it is still a relatively minor topic of interest for most in the field. Public administration today still reflects, in large measure, the founders' original concern for solving problems. Much of the field, therefore, sees itself as pragmatic without recognizing either its

potential connection to or departure from the philosophical pragmatism of Peirce, James, and Dewey.

Principal-Agent Perspective

Arie Halachmi

*Institute of Government, Tennessee State University, Nashville, Tennessee,
U.S.A. and Zhongshan University, Guangzhou, P.R. China*

INTRODUCTION

According to Barney and Hesterly, agency theory seeks to understand the causes and consequences of the conflicting goals associated with an organization.^[1] To them, agency theory is part of the literature of organization economics. Neelen suggested that the principal-agent model, neo-institutional economics on the whole, and neoclassical economics are, in fact, large families of diverse theories.^[2] These theories are related by shared analytical foundations more than they are unified theories. According to Moe, these shared analytical foundations include a focus on the individual as the unit of analysis; the assumption of rational utility maximization behavior; a concern for efficiency, optimization, and equilibrium; and a preference for mathematical modeling.^[3] As it originally developed, agency theory research focused on the relationship between managers and stockholders,^[4] drawing heavily from the property rights literature^[5] and, to a lesser extent, from transaction cost theory.^[1] The phrase “principal-agent perspective” is used here as a catch-all phrase because a complete phenomenological and epistemological discussion of the various approaches to and writings on principal-agent relationships and their antecedents in the literature on the separation of ownership and control^[4,6] are beyond the scope of this discussion.

DEFINING AGENCY RELATIONSHIPS

The principal-agent perspective views the interaction between two parties as a situation in which two actors (i.e., individuals, groups, or institutions) agree to cooperate with each other in a contractual relationship that requires the principal to pay the agent for activities the agent makes on behalf of the principal. The relationship between the two actors is characterized by the presence of agency-specific conditions:

- Conflict of interest or, more technically, negative externalities. The decisions of the agent affect both

the agent’s own welfare and that of the principal (more on that interdependency below).

- No choice when the principal cannot accomplish something on their own. The agency relationship results when the “principal” must secure the services of the “agent” through “delegation” to complete a task.
- Asymmetric information. The principal is faced with a situation of imperfect monitoring because it is impossible to observe all the actions and decisions of the agent or infer them by observing the outcomes of the agent’s decisions. Hence, the agent has some opportunity for discretionary behavior.
- The relationship between principal and agent is based on a contract.
- Actors maximize their utility functions subject to institutional constraints.
- Because principals and agents have different utility functions, activities that are mostly in the interest of one actor have adverse effect on the welfare of the other actor.
- Transaction costs are positive.

Neelen concluded that with this characterization of the agency relationship, the principal always faces questions of control in the context of information asymmetry and conflict of interest; thus, it is impossible for the principal to ensure, at zero cost, that the agent will make optimal decisions from the principal’s point of view.^[2] Earlier, Jensen and Meckling pointed out that in most agency relationships the principal and the agent will incur positive costs.^[4]

The principal incurs the cost of having to monitor the agent’s behavior. However, as noted by Arrow, some of the agent’s activities are hidden from the principal or are too costly to observe.^[7] Arrow called this “moral hazard” and pointed out that this is one source of agency problems. The other source, “adverse selection,” involves the hidden information that is available to one but not the other party.

The agent incurs the cost of bonding (i.e., of assuring the principal that certain actions inconsistent with the principal’s interest will not be taken). Jensen and

Meckling went on to suggest that the dollar equivalent of the reduction in welfare experienced by the principal due to a divergence (i.e., between the agent's decisions and those that would maximize the principal's welfare) is also a cost of the agency relationship.^[7] Jensen and Meckling referred to this cost as the "residual cost."^[4] Accordingly, they defined "agency cost" as the sum of:

- The monitoring expenditures by the principal
- The bonding expenditures by the agent
- The residual cost

As noted by Douma and Schreuder, agency relations can be found both within organizations (e.g., manager and subordinate) and between organizations (e.g., licensing and franchising).^[6] Thus, understanding the environmental variables that can influence agency cost should be of interest to practitioners and researchers alike. The problem is that most writers do not offer a conceptual framework for exploring the complex relationships among the principal, the agent, and the environmental context of their relationship.

Boorsma and Halachmi pointed out that, even though agency relations involve a hierarchy, there is a tendency in the literature to denote every dependency relation as an agency relation, including every hierarchical relation between a superior and a subordinate.^[8]

Yet, such hierarchical relations can be discussed within the time-honored Weberian framework. Second, Boorsma and Halachmi pointed out that market situations are frequently characterized by uncertainty or information asymmetry.^[8] Table 1 provides a possible summary of the different characteristics of contract and agency relationship.

A promising approach to the study of principal-agent relations was described by van der Zaal. Van der Zaal began by making two important points that help to explain the attractiveness of the principal-agent perspective for studying and understanding the challenge that can exist when services are contracted out.

First, van der Zaal claimed that principal-agent taxonomy from agency theory appears to suit the required perspective for interorganizational strategic management issues. In addition, he saw this taxonomy as a promising candidate for the development of an integrative framework in which connections can be made among environmental dimensions, such as "uncertainty" and "dependency," and intraorganizational dimensions, such as organizational resources, strategic assets, core capabilities, and core competencies.^[9] Such an inside/out approach would be complementary to strategic management, in which competitive analysis starts within the boundaries of the organization but with an outside/in perspective.

Table 1 Basic transactional patterns of contract and agency relationships

Division of labor	Contract	Agency
Formal aspect	Market	Hierarchy
Perception of actors	Isolated	Integrated
Procedural aspect of planning	Self-determination	Delegation
	Specification	Representation
		Discretion
	Discreteness	Interdependence effort
	Performance orientation	Orientation
Legal structure	Mutual consent on two individual decisions to perform	Unilateral authorization to act on behalf of principal
Necessary rules	None (fully specified contract is self-enforcing; pacta sunt servanda is not necessary but an expedient rule)	Sanctions for breach of loyalty; sanctions for non-performance of promised incentives
Revelation of individual preferences	Does not matter	Central feature
Real world paradigm(s)	Exchange of goods and services	Manager, sales agent, guardian, sharing arrangements
Basis of legitimacy	Reciprocity (mutual consent of parties)	Power delegation by 1) consent, 2) voting, 3) statute
Entitlement structure	Exchange of property rights	Horizontal split of property rights; paradigm: decision control+residual ownership/decision management

Table 2 van der Zaal framework

	Principal	Agent
Environmental uncertainty—an information perspective	1 Uncertainty about (the relation with) the agent	2 Uncertainty about (the relation with) the principal
		3 Uncertainty about the environment surrounding the principal-agent relationship
Environmental dependency—a resource perspective	4 Dependency on (the relation with) the agent	5 Dependency on (the relation with) the principal
		6 Dependency on the environment surrounding the principal-agent relationship

Van der Zaal's second claim is that agency cost reduction is not enough to explain the cooperation between the principal and the agent.^[9] The other reason for the cooperation is the incentive to create value. Van der Zaal called this concept "agency benefit" and made two propositions: 1) that by integration of the "agency benefit" concept into the principal-agent framework, it may be possible to develop a well-balanced benefit-cost framework for analyzing cooperative interorganizational relations from a principal-agent perspective, and 2) that the principal-agent taxonomy deals with three levels of analysis.^[9] The first level is the focal organization. The partner in the relationship is part of the environment and represents the second level of analysis. The environment around the principal-agent relationship forms the third level of analysis.^[9]

The conceptual framework offered by van der Zaal^[9] is summarized in Table 2. It requires us to consider the relationships among the principal, the agent, and the environment, first by considering the uncertainty of the environment (i.e., by using an information perspective as illustrated by cells 1, 2, and 3), and second, by using a resource perspective (i.e., the dependency relations as illustrated by cells 4, 5, and 6). This framework may be useful for exploring many issues and the contingencies of various administrative innovations. For example, Halachmi suggested that a principal-agent perspective is a promising framework for studying a "make" or "buy" decision such as the federal experiment with Franchise Funds [i.e., the effort to encourage federal entities to secure (i.e., buy) administrative support services from other federal entities rather than provide (i.e., make/produce) them in-house].^[10] For that matter, the

principal-agent perspective may prove useful for studying any decision about contracting out, partnership, or cooperation.

Privatization

INTRODUCTION

The privatization movement in the public sector was accelerated by the New Conservatism under the Reagan and Thatcher administrations. Basically, new conservatives value economic and political liberalism that have emphasized free competition of market system. Under liberalism, small government and small tax are preferred. According to them, welfare state imposes so much tax and regulation on free-market mechanism as to distort the free flow of capital. Thus welfare state (big government) cannot but be faced with economic stagflation under which economic depression and inflation simultaneously occur. In addition to this basic belief of liberalism, new conservatives do not neglect the weak points of market mechanism. Thus they emphasize not only free-market system but also the inevitability of government intervention. In this context, new conservatives argue for “small but strong” government rather than simply “minimal government.”

The privatization movement began from this reflection on the problem of welfare state. The rationale for privatization is government failure that public choice has criticized. According to public choice theorists, decision making in government is not made based on the principle of rationality; rather, most decisions are made by political bargain. In the political bargain process, many interest groups, politicians, and business groups are involved. And public policies produced by the process are implemented by big government. Public choice theorists consider government bureaucrats as self-interest seekers just like other business groups. As business groups pursue profit-maximization, government bureaucrats, according to public choice theorists, do “budget maximization.”^[1,2] As a result, interest groups, politicians, business groups, and government bureaucrats establish a “budget-spending coalition.”^[3] Public services provided by the budget-spending coalition cannot but be inefficient.

DEFINITION OF PRIVATIZATION

Strictly speaking, privatization means that government sells its property rights to state-owned institutions to

the private sector. For example, currently government-owned companies are being sold to private companies. Thus many services that were once provided by government are now being provided by private companies. Even international companies can buy other countries’ public companies.

In a broad sense, transition of government function can be included in privatization. For instance, government can make a contract with private companies in order to enable the companies to provide public services in lieu of government.

FORMS OF PRIVATIZATION

There are several forms of privatization. Here, four representative forms of privatization are discussed based on the Savas’ classification: contracting out, voucher, franchising, and sale.^[4]

Contracting Out

Government can delegate authority of a public service to a company via a competitive bid during a limited period. Through contracting out, government can provide better services with less cost because of competitive bids between private companies. Some state governments are using contracting-out strategy in order to stimulate public employees. Public employees can see that their jobs may be privatized unless performances of their organizations are satisfactory. When a government contracts out a service with a company, it should pay much attention to whether the company can sustain good quality of service after the service is contracted out. And government should check whether the company persistently holds to its responsibility to the citizens. Most of all, government should provide fair conditions for many private companies that are participating in a competitive bid.

Possible services that can be contracted out include public car maintenance, public hospital services, garbage collection, security services, and management of public facilities such as library, cafeteria, and other

professional facilities. According to Savas' report, the average American city contracts out 23% of its 64 common municipal services to the private sector. The average American state contracts out 14% of its activities.^[4]

Voucher

There are many limitations to a government's ability to take care of a citizen's specific demand. For instance, recipients of welfare services need very specific and various cares. By giving a voucher, government allows citizens who need a specific service to choose the service that meets their needs.

In this system, government should pay much attention to whether private companies can fairly compete with each other in the voucher market. Possible services for the voucher method include food, housing, education, health care, transportation, and other social services.

Franchising

Through franchising, government can award a company specific authority to provide a service for a limited period. A company, for example, can build a public parking lot and manage it in a public land. And the company should pay government a fee. Usually, building infrastructures is a great burden to governments. Through franchising, government can take advantage of private capital and provide better service for citizens with no great financial pressure.

Sale

Government can sell a public facility to a company. Of late, some governments have sold public-owned

companies to private companies. In the globalization age, some international companies can purchase other countries' public companies.

In addition to those four methods, there are other methods of privatizations. Table 1 shows various methods of privatization based on Savas' study.^[4]

EFFECTS OF PRIVATIZATION

In general, there are two advantages in the privatization of public services. First, privatization contributes to enhancing efficiency of government management. By transferring a portion of government function that the private sector can undertake, government is able to reduce its total size. By making government small, the private sector can play a bigger role in the total national economy. Thus privatization is known to relieve financial deficit in government. In fact, the privatization movement in America is closely related to the financial crisis of the public sector in the 1970s.

Second, privatization can give multiple choices to citizens choosing public services. Government loses its monopolistic authority in providing public services and has to compete with the private sector.

WEAKNESS OF PRIVATIZATION

The ideology of privatization is efficiency of government management. It is true that privatization has contributed to increasing the total efficiency (economic efficiency) of government management. However, it should be noted that privatization should be implemented under fair competition between private

Table 1 Institutional arrangements for providing public services

Service arrangement	Arranger	Producer	Who pays?
Government service	Government	Government	Government
Government vending	Consumer	Government	Consumer
Intergovernmental agreements	Government ^[1,2]	Government ^[3]	Government ^[1,2]
Contracts	Government	Private sector	Government
Franchises (exclusive)	Government	Private sector	Consumer
Franchise (multiple)	Government and consumer	Private sector	Government and consumer
Grants	Government and consumer	Private sector	Government and consumer
Vouchers	Consumer	Private sector	Government and consumer
Free market	Consumer	Private sector	Consumer
Voluntary service	Voluntary association	Voluntary association	N.A.
Voluntary service with contract	Voluntary association	Private sector	Voluntary association
Self-service	Consumer	Consumer	N.A.

Source: From Ref.^[4].

companies. In the same context, a certain class of people should not be excluded from the benefits of privatization. This is the issue of social equity.

Although the privatization of government function is widely preferred, it does not necessarily mean that minimal state is the best form of modern government. In other words, privatization is not equated with "small government." Even in privatization periods, citizens still want government to do more work for them. Thus just as big government brings some problems, a big private sector will also bring some more problems. Stable development of modern societies would be possible in the status of equilibrium between the private and the public sectors.^[5,6]

CRITERIA OF PRIVATIZATION

Before a public service is privatized, there are several points to be considered.

First, what is the original goal of the service that is going to be privatized? All public services have their targeted goals and recipients. If the services were provided by the private sector, would those original goals be maintained?

Second, should government really be responsible for the service? As it is well discussed by many scholars, the issue of responsibility is a very important point to be considered prior to privatization of public services.

Third, is the privatization policy of a country compatible with the societal needs and national goals of the country? It should be noted that privatization movement followed reconsideration of a welfare state in America and Britain. In other words, those developed countries already have a well-established welfare system. On the contrary, citizens in other

developing and underdeveloped countries still need more extensive public services from government.

CONCLUSION

The core of privatization strategy is to imbue the public sector with competition and innovation mind. Transfer of property rights and government function from the public sector to the private sector has been a prevalent effort to institutionalize competition and innovation mind in the public sector.

Fundamentally, management strategy of public organizations should not be the same as that of private organizations because those two organizations have different organizational goals: profit maximization and pursuit of public interest. Considering the weaknesses of privatization, it would be more desirable to find more strategies to sustain competition and innovation mind along with the privatization forms mentioned above.

Privatization and Economic Development

Bill Luker

Department of Economics, University of North Texas, Denton, Texas, U.S.A.

INTRODUCTION

“Economic development” and “globalization” are the two catch phrases for this era in capitalist history. However, globalization is a relatively new term, and until recently its discussion domain has been limited to circles of professional economists, policy theorists, and senior public and private executives at national and international levels. However, among economic and policy practitioners at other levels of government (e.g., province, state, or local level), concerns about economic development arose long before the globalizing forces that now make development in their jurisdictions more of an imperative than ever.

Descriptions of the specific ends of economic development have been as varied as the places in which developmental theories and practices have been applied. Yet, in recent economic history, one general end or goal stands out—to raise or qualitatively improve the living standards of people in a particular place or nation, relative to some set of preferred living standards in Europe, the United States, or highly affluent places in those countries. Although various measures have been proposed to gauge the results of efforts aimed at these qualitative improvements, those most commonly used by economists and policy makers have been quantitative (e.g., changes in per capita income).

Per capita income change, either based on national monetary standards or on a global “purchasing power equivalent” standard, is a convenient metric for measuring progress toward developmental ends. Despite its convenience, and because it accounts only for the economic dimension of higher living standards or levels of human functioning, it has come under increasing attack by developmental theorists in recent years.^a But it is much less controversial than the *means* by which economic development itself should be achieved. It is here, since the 1980s, that the real battle lines—theoretical, practical, political, and ideological—have been drawn in a debate about whether government

or the private sector should lead in realizing economic development goals.

Much of this debate stems from the misleading notion that large-scale developmental goals have, and generally can be, attained without government involvement. This has not been the case historically, least of all in the United States, where the public sector led the planning, and provided the fiscal wherewithal, for development projects in mass electrification, telecommunications, and agriculture (through dams, irrigation, and farm supports of various kinds), and for rail, auto, truck, and air travel that helped to create the most affluent, geographically unified capitalist market on the planet. In most places around the world, whether highly articulated capitalist economies or those where “basic needs strategies” are required, it is still the case that development projects to provide infrastructure—sanitation, roads, and other non-divisible (i.e., public), goods—are planned, financed, and carried out by public or non-profit authorities.

Nevertheless, there are clear differences in practice, and in theory, between publicly and privately led development efforts. “Privatization” is the term that encompasses the latter.

PRIVATIZATION IN PRACTICE

Privatization manifests itself in economic development as the privatization of economic development. We can see it as a generalized process that has occurred more or less everywhere since the 1970s. First, the privatization of development shifts the choice of a measure for the effects of development initiatives from broadly defined improvements in living standards—even when these are narrowly measured, again, as increases in per capita income—to increases in the absolute number or growth rate of private sector jobs. The shift in metric is not merely a move from one convenient measure to another. It is emblematic of a change both in the ends and the means of development.

Jeffrey Sachs, the noted development economist, inadvertently revealed the character of this change when he stated that in parts of the developing and transitioning world (the post-Communist states), any wage-paying job, no matter what the wage, is better than no job at all. He was correct because the goal

^aSee Ref.^[1], particularly p. 10 and Chapter 2, pp. 35–53 (“The Ends and Means of Development”) for an adumbration of his assertion that the goal of development is *more freedom* for the individuals who make up a given society, and not just more economic well-being.

of the development process, even for the most economically backward or disrupted regions of the world, has shifted from more general ones such as “improving living standards” or “providing basic needs” to those in which most if not all world economies are to be ushered into a national, and ultimately international, wage, production, and consumption nexus (i.e., the cash nexus). Private employment at a cash wage is a necessary prerequisite for this to occur.

The privatization of economic development effects just such a shift in ends, perhaps because of, or in combination with, a shift that occurs in the means by which new jobs are to be created. Most often, and even when there are indigenous firms, technologies, or other physical or human resources present (Latin America is a case in point) that may allow development along an “endogenous path,”^[2] privatized development sees new job creation as the exclusive result of “foreign” private investment decisions (i.e., by national or multinational corporations from outside the nation, region, state, city, or place). In almost every case, these public jurisdictions now use public (tax) revenue to subsidize this employment-generating private investment.

Subsidies come in many forms. In highly developed capitalist economies such as those in the United States and Europe, cities, states, and regions compete with each other to induce firms to invest in their jurisdictions with property or income tax holidays (often lasting for years); outright grants of land, cash, developed facilities, or infrastructure (roads and water); state-provided assistance with screening, hiring, and training new employees, or direct wage subsidies.

In smaller or poorer places or nations, with few resources to induce a firm to make a favorable location decision, subsidies come principally in the form of cheap and pliable labor. Government plays its part in creating new employment by ensuring low or no minimum wages, no unions, minimal workplace safety and environmental standards, and minimal or no controls on capital mobility or the repatriation of profits from low-wage enterprises to the corporation making the investment.

As one local mayor in the poverty- and depression-stricken state of Tennessee put it in the 1930s, such is the process of “buying payroll.”^b Indeed, this aspect of the privatization of economic development on a global scale has its modern roots in poor communities of the South, West, and New England regions of the United States. Beginning in the early nineteenth century, they attempted to solve local poverty and unemployment problems by subsidizing the location of new manufacturing firms to their communities. Much later, as U.S. government aid to states and cities

declined throughout the 1970s and 1980s, local governments became more concerned than ever with creating new streams of revenue for needed public investments by expanding their local bases of employment and taxable property. The practice of “buying payroll” then spread throughout the United States, and ultimately to the rest of the globe, as aid from the developed to the developing world also declined relative to an apparently relentless flow of capital in the opposite direction.

Like the shift in ends that comes into view alongside the shift in metrics, the shift in the means of development, as embodied in the practice of buying payroll, is critical because it involves a drastic shift in public fiscal priorities and allocations. Its mechanisms tend to constrain government development activity both directly and indirectly, by siphoning public resources away from infrastructure investment, or from direct income or wage support aimed at increasing consumption and employment broadly throughout a nation or region.^c Through development “incentives,” at least a portion—estimates vary—of those resources are instead placed in the hands of private corporations or entrepreneurs to reduce their production costs, increase their profits, and make it more likely for them to create new jobs.

Additional pressure is brought to bear on the public fisc of smaller or poorer nations, regions, or cities when efforts to privatize the production and delivery of services that had been the province of the public sector (e.g., transport, sanitation, social services) are also pursued as part of the privatization of development. In these places, reducing the size of government, in terms of both employment and expenditures—including any income support to workers and families mentioned earlier—is often a condition for continued financial aid from the International Monetary Fund or World Bank. Government is thereby further constrained from development activity even as an employer of civil servants or as an employer of last resort. Ultimately, then, the privatization of development reduces the role of many national and subnational governments in the development process to one of support for, and dependent reliance upon, private investment to generate employment.

It could be argued that this is not a new circumstance because governments have subsidized private industry in one form or another for as long as private

^bSee Ref.^[3].

^cIn the United States, these programs have included social security, Aid to Families with Dependent Children, the “old” welfare system or individual subsidies to poorer workers like the Earned Income Tax Credit (a so-called negative income tax). In other countries, both developed and developing, the size and scope of these income and wage support programs has been much larger.

industry has existed. But among other differences, perhaps the decisive one is that subsidies granted to private industry by subnational governments under a privatized developmental scheme aim explicitly to benefit one particular place, regardless of the effects on other places within a given nation or region. More than one observer has pointed out, for example, that the great migration of manufacturing firms and jobs that occurred between 1960 and the present, from the U.S. Midwest to the South and West, and eventually, to Mexico and East Asia, has been facilitated and accelerated by the market-like process of “competition” between regions for new industries and jobs (e.g., Ref.^[4]) that the privatization of development creates. In this case, the competition for a privatized “unit of development” results in clear economic winners and losers at national, regional, and local levels.

By contrast, to return to the case of the United States, central government aid to the private sector for development purposes was traditionally disbursed with broad national goals in mind. The railroad land grants of the 1870s and 1880s furthered the settlement of the western half of the continental United States, with broad and incalculably large public benefits. Likewise, the U.S. government’s loan guarantees to the Chrysler Corporation in the mid-1970s saved hundreds of thousands of jobs not just in the industrial Midwest, but throughout the nation.

THE IDEOLOGY OF PRIVATIZATION

The public sector in a capitalist economy has been characterized as “a means of organizing the provision of some goods and services collectively rather than individually.” In 1924, however, John R. Commons saw it as much more than that:

[The] state also proportions the factors over which it has control. It opens up certain areas, localities, or resources, instead of others.... It encourages or protects certain businesses or classes of business, certain occupations or jobs, rather than others. It restrains certain activities deemed detrimental to the whole. Its proportioning of factors is the proportioning of inducements to individuals and associations of individuals to act in one direction rather than other directions.

Public economic problems thus involve the distribution and redistribution of resources, as well as opportunities for profitably appropriating those resources. These problems are inherently political; as such, they are resolved through political means. It is not surprising, then, that at the heart of privatization in economic development (and in all other economic

matters) is a political movement whose ideological substrate is a thorough-going, distinctly North American—and more recently, British—doctrine of *privatism*^d that has pervaded economic habits of mind since the founding of the United States. As Veblen^[5] pointed out, these principles

of natural (pecuniary) liberty... find [their] most unmitigated acceptance in America.... Nowhere else has the sacredness of pecuniary obligation so permeated the common sense of the community and nowhere else does pecuniary obligation come so near being the only form of obligation that has the unqualified sanction of current common sense.

The most radical and now most popular variant of this doctrine has been distilled from selected writings of Bentham, Smith, and James Mill, to wit, that all welfare flows solely from private pecuniary gain, and the right of the individual to pursue this desideratum dominates all others. In considering problems of economic development, its relevant corollary is that because government activity is not disciplined by a pecuniary motive, it can be nothing but a dead weight on national, regional, and individual economic performance. Its activities must therefore be strictly curtailed, lest they interfere with private economic endeavor. Soros^[6] called this philosophy “market fundamentalism,” and it drives all current efforts to privatize the process of economic development.

THE CASE FOR PRIVATIZATION

Like many of the sweeping changes in economic policy and practice we have witnessed in recent years, the ideological justification for privatizing economic development has been buttressed in theory by the standard microeconomic model of the market. The state of Mississippi, for example, began its privatization program in 1936, calling it the “Balance Agriculture With Industry” (BAWI) program. One well-respected regional economist^[7] later wrote that its intent was to “provide full employment for the available able-bodied manpower of working age” in Mississippi because “opportunities for off-farm employment [were] only a small fraction of the number needed.” He also reported a study^[8] of the BAWI program where 12 communities who “purchased” new industries received “an average return [on their investments]... of 800 per cent per year.” Moes asserted that these were results that “almost any community that has un- or

^dThe term is somewhat novel, but not entirely new.

underemployment could achieve if it were willing to do what it takes to 'buy' industry."

Moes's justification for this hyperbolic statement was straightforward. Industrial enterprises make decisions about where to build new plants based on production costs at different locations. Governments could attract new businesses to their areas by competing with each other to create production cost differentials large enough to influence a firm's location decision. When communities "buy payroll," local governments become "income-maximizing corporation[s] making an investment the returns of which are measured in terms of aggregate income gains."

Bartik^[9,10] and others (e.g., Refs.^[11,12]) argued that the "purchase" of private sector jobs can cause one-time increases in local employment, and these increases have long-term benefits for communities because labor markets are subject to hysteresis effects. Bartik believed that hysteresis occurs when "an economy's equilibrium unemployment rate [is] permanently increased by a temporary recession, or lowered by a temporary boom." "If this is true," he continued, "then macroeconomic policies that affect... short-run performance... may affect... long-run performance."

Bartik estimated the impact of employment growth on unemployment, labor force participation, weekly hours worked, real wages, real earnings, and income distributions in 114 local labor markets in the United States. Using both aggregate and microlevel data, his analyses supported the hysteresis hypothesis. First, he found that local employment growth—again, purchased from the private sector with tax expenditures—could lower a given area's unemployment and raise its labor force participation rate for as long as 8 years. Second, for every additional 100 new jobs created by any given job purchasing policy, 7 will go to local residents who otherwise would have been unemployed, and 16 to residents who otherwise would not have been labor force participants. The rest go to in-migrants.

Third, although "a rising tide lifts all boats" and differential impacts "are relatively small compared to the mean long-run effect for the sample," the benefits of job growth vary across races and age groups. It helps African Americans, young workers, and less-educated workers "advance to better-paying occupations," who "are [then] able to keep [them] even in the long-run." Employment growth increases real earnings and tends to equalize income distribution. These effects were so heavily biased in favor of "lower-earnings males" (e.g., African Americans and the less educated) that "overall effects of local growth on the income distribution," even after the almost inevitable increases in property values that result from job-purchasing policies are factored in, were "at least modestly progressive."

Finally, Bartik stated—and this was not tested in his empirical analysis, but justified on theoretical grounds—that job-purchasing policies by nations and communities can improve overall economic welfare at the national level. Interstate and intermetropolitan competition for the purchase of economic development can redistribute employment and employment growth from areas with low unemployment to those with high unemployment. This can result in a net gain in national economic welfare because the marginal benefit of an additional job in the latter community is higher than the marginal cost of losing a job in the former. He also averred that the probable net effect of competition for jobs increases the aggregate national level of subsidies to business, which he views as subsidies for labor demand. The higher their overall level, the larger the number of workers that businesses hire, and the faster national employment will increase.

THE CASE AGAINST PRIVATIZATION

Overall, Bartik believed that the changes wrought by the privatization of economic development will improve the lot of poor people in poor places. Yet, the market pressures imposed on the public sector in recent years have never been shown to increase the well-being of the poor. Hysteresis plausibly works in both directions.

Moreover, since its conception, the microeconomic justification for privatizing economic development with a "market for jobs" has been questioned by a host of analysts. An essential feature of the original argument was that given unimpeded subsidization by all communities and nations,

a rational subsidization policy would mean that [each] community acts as a discriminatory seller of labor, i.e., as a monopolist who has full discriminatory power. This power derives from the presence of scarce immobile resources within the community... and the community would never offer more than the minimum necessary to attract a given industry.^[7]

Thompson^[13] vigorously attacked this claim. "Had [Moes] but turned this conclusion around," he wrote, "it would have seemed more in accord with the economic facts":

Whether one considers the entire nation or a particular region, the number of new industrial plants established in any year is small in comparison to the large and constantly growing number of communities actively courting new industry. *Therefore, the matter of comparative numbers alone would place site-seeking firms in a stronger bargaining position than industry-seeking communities. The average firm would have*

greater withholding power than the typical community, for the community would ordinarily need new industry much more than the firm would need any one community for its plant site (my italics).

Thompson concluded that “if either participant in the bargaining over the terms of a subsidy would be in a position to act as a perfectly discriminating monopolist, it would almost certainly be the industrial firm.” A site-seeking firm would play one community against another, and use its superior knowledge and withholding power to extract the largest subsidy possible. The “price” of new jobs for any given community—the value of the development incentives—would not only be much higher than predicted by Moes, but also the monopoly power of the seller would not be easy to break. “The potential barriers to competitive pricing in this hypothetical ‘market’ for subsidies appear to this writer to be...formidable,” Thompson said. “If labor markets are marked by various imperfections, the same could be said about the subsidy ‘market’”:

[it] would consist of relatively few, sporadic transactions, and community representatives would tend to be poorly informed as to such factors as the market situation confronting the industrial prospect, the locational advantages and disadvantages of the community for this particular firm, the amounts of subsidy offers by competing communities, etc. This lack of relevant information on the part of communities would be aggravated by the atmosphere of secrecy in which the process of plant site selection is typically conducted.

The most important point for poor communities or nations seeking new industries and jobs, Thompson asserted, is that more affluent places would have a distinct advantage in any market for new jobs or industrial enterprises. “The poverty of many depressed, labor-surplus communities and nations would severely handicap them in bidding competitively for new industry” if the size of a subsidy were the determining factor in any specific case (see Ref.^[13]).^e This assertion is supported by data about the spatial distribution of foreign direct investment by transnational corporations in recent years, which has overwhelmingly favored rich countries and regions within them.^[16,17]

Since the 1960s, other evidence from research on the effectiveness of development incentives in improving local, regional, or national economic welfare buttressed Thompson’s case. Development incentives to

private firms were not a significant determinant of industrial location or interregional manufacturing employment growth,^[18–20] and their benefits to smaller and poorer places were in no way as unambiguously positive as Moes and later analysts such as Bartik contended. Benefits and costs were shown to vary with the assumptions and methods employed to assess the effect of development incentives, and with the type of incentive that was being evaluated.^[20–27] Thompson^[13] observed that the effects of development incentives were detectable, if at all, only at the stage of a location decision where two towns of roughly equal desirability were being compared by a site-seeking firm. Most, if not all, the studies of plant location were carried out at the interregional level, a point recognized by McMillan when he stressed the distinction between “determinants of plant location,” a set of variables that differ interregionally, and the “reasons manufacturers choose a plant site,” a decision influenced by local factors, some of which might include incentives.

WHENCE PRIVATIZATION?

Given the conflicting evidence, the benefits of the privatization of economic development are ambiguous for communities and nations seeking increases in employment and improvements in their citizens’ economic welfare. Nevertheless, in the world of economic development practitioners and government officials at national and subnational levels, there is no debate. They have completely embraced the process.

Seemingly unaware of this fact, academic researchers have continued to focus on whether development incentives, considered apart from the more general process of privatization, contribute significantly to changes in industrial location patterns. This question has become largely irrelevant, as more communities and nations have begun to compete with each other to lure new industries to their jurisdictions. In fact, participation in competitive bidding for new manufacturing plants or corporate facilities appears to no longer be a voluntary process.

Benson,^[28] arguing that “taxes matter” in the geographic distribution of employment growth, inadvertently stumbled upon this point. He reasons that because subnational jurisdictions now compete with each other on a routine basis to attract business activity, that “[this] competition prevents taxes from varying sufficiently enough to have a statistically measurable impact on relative economic growth....” He argued further that the spread of competition for new industrial enterprises imposes a “market constraint”^[28] upon policy makers worldwide, forcing

^eRubin and Rubin^[14] made this point in a more recent publication. Bowman^[15] also found that cities with high degrees of fiscal stress were much more likely to use development incentives—and a wider array of them—than cities in relatively good fiscal health.

them to keep taxes, wages, and working conditions in line with those of other regions or nations, either through legislation or through the provision of development incentives.

The net effect of the privatization of economic development, as we noted earlier, is to place constraints on the size and fiscal health of the public sector. Moore and Pagano^[29] argued presciently that these constraints create “dismal” prospects for public finance in the 1990s and beyond:

Localities [and small or poor nations] faced with already difficult fiscal problems find themselves utilizing scarce debt capabilities for purposes that may be considered less than ideal public investments (e.g., a movement away from traditional infrastructural purposes); less able to compete effectively in a growing tax exempt market; forced to raise interest rates (and therefore future debt service burdens) to compete with taxable corporate bonds; and providing tax benefits in the form of...privately-oriented subsidies that further limit current receipts.

With narrowed national or international credit options, and uncertain prospects of outside assistance in the near and long term, the only apparent alternative for local and national governments in the developed and developing world is to stimulate private sector growth so that jobs, income, and the base of public revenue-generating wealth can expand.

The market for industrial enterprises takes on a special importance in this setting. It is not simply a market for industrial plants, but in the most general sense, a market where governments attempt to buy private investment to fund public services and public infrastructure. “Development” becomes a divisible commodity whose price is determined by market-like processes. The market for industrial enterprises thus appears as a key feature of the privatization of the public sector itself. It is a way to impose market-like mechanisms^[30] upon public bureaucracies and political processes, to transform public goods into private ones.

As we said, there is conflicting evidence about the degree to which even private sector growth is spurred by development incentives. Yet, there has been almost no discussion about the effects on the public sector of the transformation of economic development into a private good through the imposition of a market for industrial enterprises and jobs. It appears that the transformation of economic development into a divisible and saleable commodity has contributed to slower public sector growth, and declining levels of investment in public needs at all levels of government. In many parts of the developing world, where public authorities are often the only source from which investments in basic needs such as clean water, transport, and health

care are available, these trends have and could be harmful to human, as well as economic, development.^[31]

Even more fundamentally, given the “private” (i.e., secretive) nature of the negotiations carried out between government officials and corporate executives seeking incentive packages in the privatized market for economic development, what effect has its emergence had on democratic public participation in decisions about development? After almost 60 years of debate, this is the crucial question, but the one least frequently asked. If we value democratic participation intrinsically, by defining development not in merely economic terms but as improvements in overall human functioning—including a person’s ability to participate in the political life of one’s community—it appears initially that the answer is not what we might want to hear.

Privatization and Public-Private Partnerships for Local Services

E. S. Savas

*School of Public Affairs, Baruch College, City University of New York,
New York, New York, U.S.A.*

INTRODUCTION

This article defines and describes the various forms of privatization applied to local government services, the rationale and opposition to privatization, and evidence on the results and extent of privatization. It discusses the logical expansion of privatization to public-private partnerships and the emerging concept of government by network.

Local government services are a daily necessity. People expect an abundant flow of clean water from the kitchen faucet and their household garbage to disappear from the curb. They want expedited construction of needed new roads. They demand efficient, effective, and equitable provision of local services, and this pressure to perform has forced local governments to turn to alternative service arrangements as an important strategic tool to improve service delivery.

DEFINITIONS

Introducing competition to monopolistic public agencies was proposed in 1971 as an explicit, unconventional approach to reduce costs and increase efficiency of local government services.^[1] This policy quickly caught on and focused on competitive contracting with private companies for services, and the concept was termed “privatization.”

Privatization can be defined broadly as relying more on the private institutions of society and less on government to satisfy people’s needs.^[2] It is the act of reducing the role of government and increasing the role of other societal institutions in producing goods and services and in owning assets. These institutions are the market, voluntary groupings of all kinds, and the family; together these constitute the private sector. Instead of expecting government alone to address societal needs, privatization takes advantage of the capabilities of these other institutions and aims at a new balance, a better allocation of roles and responsibilities among these four societal institutions.

Three broad methods are used to privatize government services and government-owned enterprises and

assets: delegation, divestment, and displacement. Delegation means that government is responsible for a service but utilizes the private sector to deliver it. Divestment means that government disposes of an asset, activity, or enterprise. (Often “privatize” is used narrowly to refer only to divestment.) Displacement occurs when a private for-profit or non-profit organization starts providing a service and gradually replaces a government service. The particular techniques within these three general methods are listed and illustrated in [Table 1](#). One can combine techniques, as is illustrated below.

Contracting out, also called outsourcing, is the most common privatization technique for local services. Outsourcing is a common practice in the private sector where a firm contracts to have a non-core activity provided by another firm for whom that activity is in the latter’s core area of competence. Examples include payroll processing, advertising, warehousing, and operating the company cafeteria.

Inasmuch as the basic idea is to introduce competition in monopolistic government services to improve performance, “competitive sourcing” has replaced “privatization” both as the term of choice for contracting and in practice: competition for service delivery is open to the government agency itself and not only to outside bidders.^[3] (“Managed competition” is another term for this process.) It is often found that after losing several rounds of competition and seeing its service area shrink as private contractors take over part of the service, the public agency gradually adopts the efficient practices of the private firms, becomes competitive, and starts winning some bids. The city of Indianapolis became a model of sensible privatization and managed competition during the administration of Mayor Stephen Goldsmith.^[4] When the service is retained in-house after competitive sourcing, this cannot logically be called privatization.

It is increasingly common to refer to “public-private partnerships,” a less contentious term than “privatization.” A public-private partnership is defined broadly as any arrangement between a government and the private sector in which the latter performs traditionally public activities. Increasingly, this term

Table 1 Forms and examples of privatization

Form	Examples
Delegation	
By contract	See Table 2
By franchise	Bus service, water supply, long-term operation of toll roads
By lease	Stadiums, parking garages, golf courses, airports
By subsidy (grant, low-interest loan, tax status, etc.)	Low-income housing, social services, cultural institutions, private bus lines
By voucher	Food stamps, housing, day care, schooling
By public-private partnership	Local-government infrastructure: toll roads, bridges, airports, school buildings, water and wastewater-treatment plants, correctional facilities
Divestment	
Sale	Tax liens on foreclosed buildings, excess land, city-owned businesses, public hospitals, city-owned TV and radio stations in New York
Free transfer	Example: Buenos Aires privatized by giving its buses to the drivers
Displacement	
Default	Van services and gypsy cabs when municipal bus service is inadequate; churches and other non-profits operating social services, soup kitchens
Withdrawal	A city can close payment offices and enable citizens to pay taxes, water bills, etc., over the telephone or Internet using private billing services
Voluntarism	Voluntary services when government programs are deemed inadequate; Adopt a Highway; Adopt a School, Adopt a Park
Deregulation	Appropriate deregulation of child day care to allow more private provision; elimination of rent controls to encourage housing construction and reduce the need for public housing

Adapted from Savas, E.S. *Privatization in the City: Successes, Failures, Lessons*; CQ Press: Washington, DC, 2005; 18.

is applied more narrowly to a complex undertaking involving government and several commercial partners to finance, plan, build, and operate—for up to 99 years—a large, long-lived, revenue-generating infrastructure project (e.g., highway, bridge, water-treatment plant, or airport). It also applies to an arrangement where a public agency contracts with a non-profit entity that also raises funds from private donors (including corporations) to supplement the contract payment. For example, Central Park in New York City is managed and maintained by the non-profit Central Park Conservancy—formed to rescue the Park when the government failed to maintain it properly—which raises four times as much money annually from donors as it is paid under its city contract.^[5] (This example illustrates privatization by displacement via default, voluntarism, and contract.)

Goldsmith and Eggers point out that public-private partnerships can involve relationships among a variety of public, non-profit, private, and other governmental bodies to achieve a public purpose; they call this “government by network.” Designing and managing such increasingly common organizational networks calls for a very different set of skills than conventional hierarchical government.^[6]

THE RATIONALE FOR PRIVATIZATION

The most compelling reason for contracting, or outsourcing, is increased efficiency. The benefits derive ultimately from introducing competition and challenging in-house monopolies of conventional public services. Privatization is also useful when a city wants rapid startup of a new service or to avail itself of specialized expertise.

Communities that are too small to realize economies of scale through in-house provision of a service may be able to hire contractors who service several communities and thereby can reap those benefits of scale, incur lower costs, and charge less than the cost of in-house work.

Privatization by divestment is popular because it raises money by selling surplus property and government businesses that are not core government functions. For example, New York City government sold a hotel, vacant lots, garages, thousands of residential buildings, a television station, and two radio stations. The state of New York sold golf courses, armories, and underutilized mental-health facilities. Divestment thrusts formerly government-owned enterprises and properties into the competitive marketplace.

OPPOSITION TO PRIVATIZATION

Privatization is philosophically attractive to many who believe that government has grown too dominant in society and should be limited in size and scope. It is philosophically repugnant, however, to those of the opposite persuasion. Ideological opponents fear a loss of democratic accountability under privatization, a diminution of government's role, a loss of common values, and growing inequality. They discern and reject any implication that public managers and employees are self-serving, profit-maximizing bureaucrats.^[7] They believe that government cannot control contractors and enforce contract specifications. And indeed, government must be a smart buyer of contract services, an attribute not always to be found and that must be cultivated.^[8] They point to the possibility of corruption, bribery, collusion among private firms, or extortion of private firms by government officials.

Market failure can stymie privatization because ideal markets require competition, perfect information, and no externalities. Indeed, favorable conditions may not exist, but market failure must be weighed against government failure. In any event, privatization is situation specific, that is, the advantages and disadvantages depend on the particular service and its setting.

Displacement of public employees is often cited as a barrier to privatization, but workers are rarely discharged when a service is contracted out; attrition and early retirement are the rule, and contractors are usually eager to hire most of the current employees.

The strongest opposition to privatization comes from public-employee unions, who fear a loss of jobs and dues-paying members. They challenge the evidence of the numerous studies, asserting that they ignore the true cost of the transition to a private contractor and that the performance of the contractors has not been adequately monitored and measured.^[9] Middle managers in the public sector are also apprehensive about privatization, afraid that they will be released or downgraded. Opposition takes many forms, ranging from the familiar kinds of labor actions up to and including assassination.^[10]

EXTENT OF PRIVATIZATION

It is difficult to survey local governments en masse and uncover all the privatization cases, although it has been done for Anaheim, California, and New York City.^[11] It is much easier to survey the extent of contracting, however, and comprehensive data are available. Private contractors provide almost all local government services, and essentially every local government contracts for some services.^[12] The most common ones are listed in Table 2. Local governments use only their

Table 2 Extent of privatization of most commonly contracted services

Service	Percent of cities
Vehicle towing and storage	83
Legal services	53
Labor relations	53
Residential refuse collection	49
Solid waste disposal	41
Ambulance service	37
Tree trimming and planting	37
Street repair	35
Bus system operation	30
Traffic signal maintenance	24

Adapted from Morley, E. Local government use of alternative service delivery approaches." In *Municipal Yearbook 1999*: International City/County Management Association: Washington, DC, 34-44.

own personnel for half their services, both public employees and contractors for 23% of their services, and only private firms for 18%.^[13] Contracting more than doubled, increasing by 121% between 1982 and 1992 in the 596 local governments where comparable data were available,^[14] but may have leveled off recently.^[15] Moreover privatization diversity also increased, that is, more of the different forms of privatization (contracting, vouchers, franchising, volunteers, and self-help) were being used.^[16] Several cities eschew public employees almost entirely, using contractors for all but public safety functions.^[17] A city in receivership was restored to financial health in four years through total privatization.^[18]

THE RESULTS OF PRIVATIZATION

The most studied forms of privatization are contracting for municipal services and divestment of government-owned businesses and property. The consensus is that—properly carried out—privatization by competitive contracting increases the efficiency of local services.^[19] In the most exhaustive compilation of studies, Hodge concludes, "There is little doubt the weight of evidence appears to support the notion that on average the unit costs of services are reduced through competitive tendering of public services."^[20] After studying two decades of worldwide contracting experiences, Domberger and Rimmer conclude that reduced service costs "appeared to be consistent over this period of time, throughout all the countries reviewed, and over all levels of government."^[21] Savings range as high as 35% for public works functions, which are easiest to outsource and to measure.^[22]

With respect to the other major form of privatization that has been studied extensively, divestment, the incentive is self-evident: revenue is realized as governments sell properties they do not need or businesses that do not perform core functions of government. Moreover performance of the enterprises generally improves upon divestment. Because there are relatively few government-owned business enterprises in the United States, the evidence comes from comparisons of public and private enterprises abroad^[23] and from before-and-after studies of newly privatized government-owned enterprises abroad.^[24]

The other specific forms of privatization listed in Table 1 have not been studied much because each case is different, but the forms are popular, and surveys indicate that local governments are using them more.^[25]

The observed benefits of privatization are generally achieved not by paying lower wages but by increasing productivity, that is, realizing more work output per hour of effort. This is obtained in different ways depending on the particular service. It is usually the result of more capital investment, better equipment and technology, better work organization, and better management: managers are free of the constraints typical of the public sector and can assign and supervise employees better and can reward and promote good workers and withhold rewards from—or dismiss—unsatisfactory ones.^[26] The higher productivity of a privatized service is often associated with better but fewer employees who receive higher wages.

HOW TO PRIVATIZE

The processes involved in privatization by divestment^[27] and through public-private partnerships^[28]

are well documented. The steps in contracting for services are shown in Table 3. Contracting is not a simple issue. One has to consider transaction costs, principal-agent problems, market imperfections, nature of the contract, the basis for evaluating bids, the ability to monitor and enforce contractor performance, and the basis for contract termination or renewal, for example.^[29]

Segmenting the service into smaller units or service districts and inviting bids for each district can foster competition. Limiting the number of units that any one contractor can be awarded and staggering contract start dates so that 3-year contracts are up for bid every year for some districts encourage bidders to keep competing. Of paramount importance is developing a transition plan for existing public employees who will be affected by the privatization. Common approaches are to privatize gradually—that is, only part of the service at a time—and rely on attrition; to require the contractor to hire existing employees; to give severance pay and early retirement; to give released employees preference in future openings; and to save vacancies that occur in other departments during the planning period and then fill those vacancies with the affected employees after the contract goes into effect.

CONCLUSION

Privatization is a common good-government practice, widely used by officials of all political and ideological persuasions. Many particular techniques are available. Privatization generally leads to significantly better performance provided that good management practices are followed.

Table 3 Steps in contracting for services

1. Introduce the idea of privatization by contracting
2. Select a service that is a good candidate for contracting
3. Conduct a feasibility study
4. Foster competition
5. Request expressions of interest or qualifications
6. Plan the employee transition
7. Prepare bid specifications
8. Initiate a public relations campaign
9. Engage in competitive sourcing ("managed competition")
10. Conduct a fair bidding process
11. Evaluate the bids and award the contract
12. Monitor, enforce contract performance, evaluate

Privatization and Reinvention Paradigms for State Governmental Administration, Consequences of

Julia E. Robinson

J. Robinson Enterprises, Inc., Boise, Idaho, U.S.A.

INTRODUCTION

The reinvention movement burst onto the public administration scene with the publication of *Reinventing Government: How The Entrepreneurial Spirit is Transforming The Public Sector*.^[1] In their best seller, Osborne and Gaebler take up the instrumental question of “How to do government?” The term “reinventing government” quickly became the mantra for government reform advocates. The impact of reinvention themes on public policies discussion at all levels of government in the nineties cannot be underestimated.

The fundamental premise of these reinventionists is that traditional approaches to government, designed at the beginning of the twentieth century during the Progress Era and New Deal, are no longer effective for a postindustrial knowledge-based global economy. Theorists in reinvention argue for a new “paradigm” where the locus of control for design and delivery of services should be shifted whenever possible from the governmental agency to the community or empowered citizen. This new approach to government focuses on results not on rules, developing clear agency missions and goals, decentralized authority, and utilizing market mechanisms to deliver services. In entrepreneurial government, the public sector becomes the catalyst for the changes. The role of public employees is to define problems, and assemble the necessary resources to get the job done. In practice, however, the term “reinvention” has come to mean “privatization” of government services for many politicians and practitioners. The ultimate result of reinvention is that many government services are privatized, and agency personnel become contract managers.

Reinvention is a public administration theory and an approach to government service delivery. In their writings, public administration theorists in general have expressed a sense of unease that the reinvention theory moves American public administration further away from fundamental democratic values of citizen involvement, social justice, and equity while over-emphasizing efficiency and self-interest.

The popularity of reinvention is only understandable within the political and social context of the early

nineties. The popularity of reinvention can be explained by a confluence of influences, resulting in a shift from government solutions to market solutions. The millennium brings a new confluence of variables, which suggests that while reinvention strategies have been successfully enacted in federal and state governments, U.S. citizens are more willing to debate the “appropriate” role of government in providing public goods and public protection today than they were even a year ago.

OVERVIEW OF THE REINVENTION PARADIGM

The reinvention movement burst onto the public administration scene with the publication of *Reinventing Government: How The Entrepreneurial Spirit is Transforming The Public Sector*.^[1] In their best seller, Osborne and Gaebler take up the instrumental question of “How to do government?” Their focus is day-to-day operations. Osborne and Gaebler argued that in a time of declining public resources, government must move from a bureaucratic model to an entrepreneurial model.

Osborne provided further clarification of the reinvention approach through actual examples in *Banishing Bureaucracy*.^[2] Osborne’s definition of reinvention is: “The fundamental transformation of public systems and organizations to create dramatic increases in their effectiveness, efficiency, adaptability and capacity to innovate. This transformation is accomplished by changing their purpose, incentives accountability, power structure and culture.”^[2,13,14]

The fundamental premise of these reinventionists is that traditional approaches to government, designed at the beginning of the twentieth century during the Progress Era and New Deal, are no longer effective for a postindustrial, knowledge-based global economy. They see the traditional governmental model as bureaucratic based on formal rules and regulations, with line-item budgets and a large number of employees providing the services in hierarchical structures. Theorists in reinvention argue for a new “paradigm,” where the locus of control for design and delivery of services should

Table 1 Contrast of traditional bureaucratic and reinvention themes

Traditional bureaucratic government	Reinvention government
• Rational-legal authority based on the rule of law • Hierarchical administrative structure with formal lines of authority. Top-down administration • Division of labor • Authority lies with the position rather than the individual • Established channels for communication • Ordered by written rules: apply general rules to specific cases, resulting in fair and impartial results • Standardized and impersonal • Administrative processes used to deliver services • Specialized administrative functions are provided for based on objective criteria	• Catalytic government: steering rather than rowing • Community-owned, focused on empowering rather than serving • Service delivery through competitive processes • Mission driven rather than rule driven • Results oriented: funding outcomes rather than inputs • Customer-driven: meeting the needs of the customer, not the bureaucracy • Enterprising government: earning rather than spending • Anticipatory government: prevention rather than after the fact cure • Decentralized government: emphasizes employee participation and teamwork • Market-oriented government leveraging change throughout the market

be shifted whenever possible from the governmental agency to the community or empowered citizen. This new approach to government focuses on results not on rules, developing clear agency missions and goals, decentralized authority, and utilizing market mechanisms to deliver services. In entrepreneurial government, the public sector becomes the catalyst for the changes. The role of public employees is to define problems and assemble the necessary resources to get the job done.

Reinventionists call for entrepreneurial managers who have authority over budgets to shift resources from areas of lower productivity to areas of greater yield, provide incentives to employees and to programs, and focus on leading (steering) rather than service provision (rowing). In this model, government becomes a purchaser of services through competitive processes, meaning that many traditional government roles are bid out. In the pure reinvention model, the public sector may use the public sector, private sector, voluntary non-profit sector, or a combination of any of these as the actual service provider. In practice, however, the term “reinvention” has become synonymous with “privatization” of government services for many politicians and practitioners. The ultimate result of reinvention is that many government services are privatized, and agency personnel become contract managers.

Table 1 presents a summary of major reinvention themes contrasted with traditional bureaucratic themes.

IMPACT OF REINVENTION ON THE PUBLIC AND ON GOVERNMENT AT ALL LEVELS

Osborne’s and Gaebler’s book, *Reinventing Government*, had a broad-based impact, appearing on the New York Times’ best-seller list for four editions in

the first year of publication. During the first two years after publication, there were more than 400 newspaper articles, journal articles, books, conferences, and even advertising highlighting “reinvention” at all levels of government.^[3] By the late 1990s, the book had sold around half a million copies and had been translated into 15 languages.^[4] Reinvention themes in the early 1990s struck a popular cord with elected officials and members of the general public, who had grown frustrated by what they perceived to be large bureaucratic structures at all government levels (federal, state, county, local), and which were unresponsive, inefficient, and not focused on citizen needs.

The term “reinventing government” quickly became the mantra for government reform advocates. The term “reinvention” was adopted by the general public and was incorporated into then President Bill Clinton’s policy agenda through the first National Performance Review headed by Vice President Gore with consultation from Osborne.^[5]

The reinvention paradigm also permeated state and local government discussions. Scores of state and local politicians ran for office on reinvention themes across the country. Numerous efforts were made by governors and state legislators to incorporate reinvention concepts into state government management. The most well-known theoretical discussion of the potential for reinvention strategies in state and local government is the work of the Winter Commission, named after its chair, the Honorable William F. Winter, former Governor of Mississippi. The Commission began in 1991 and submitted its report to President Clinton in 1993.^[6]

As illustrated by the previous discussion, the impact of reinvention themes on public policies discussion at all levels of government in the 1990s cannot be underestimated. In addition, there was a great deal of debate

in the public administration literature on the positives and negatives of reinvention concepts in terms of future directions of American public administration. (For some examples of this literature, see Refs.^[4,7-9].)

Key questions raised by public administration theorists include but are not limited to the following:

- Do the themes of reinvention correctly capture the current body of public administration literature and create a body of sustainable theory?
- How much decentralization is enough?
- Is a government customer the same as a citizen? Can one assume that the collective self-interest of individuals will result in the overall public good? And, if not, how is citizen involvement sustained in the reinvention approach?
- In service agencies, how are decisions of public goods versus market mechanisms made to insure public accountability? Who determines what and from whom?
- What is the role of regulatory agencies in the reinvention model? Are the bodies being regulated (probably business) the customers, and, if so, what impact does that have on public safety and cost effectiveness for citizens and not for businesses?

Public administration theorists in general have expressed in their writings a sense of unease that the reinvention theory moves American public administration further away from fundamental democratic values of citizen involvement, social justice, and equity, while overemphasizing efficiency and self-interest. At the beginning of the new millennium, the jury may still be out on the value of reinvention for American public administration theory. It is clear to every government practitioner that reinvention has left a mark in the structure and process of government.

ROOTS OF REINVENTION

The above discussion demonstrates that reinvention is both a public administration theory and an approach to government service delivery. It is important to note that the concept of making government more like business is not new. In the 1980s, Graham Allison,^[10] in a famous article comparing the differences between public and private management, used the experiences of managers who have served in both public and private capacities to draw a different conclusion than “reinvention.” He concluded that public and private management are different, and public management is harder.

Thus, the popularity of reinvention is only understandable within the political/social context of the early 1990s. The popularity of reinvention can be

explained by a confluence of influences resulting in a shift from government solutions to market solutions. Invisible and omnipresent, cultural values impinge upon and guide societal choices. By the early 1990s, an array of factors converged to enhance the appeal of reinvention as a viable political approach. The shift in cultural acceptance of reinvention can be traced to these changing dynamics.

First, in the 1980s, the business management philosophy writers began emphasizing change agents and the search for excellence in business settings. (For some examples of this genre, see Refs.^[11,12].)

Second, since the late 1960s, there has been an ongoing political transformation in our country. Citizens increasingly have moved away from voting for politicians who supported big government, such as former President Lyndon Johnson, to conservative politicians who see government as a necessary evil, typified by former Presidents Ronald Reagan and George Bush. This political transformation was documented with tax revolts by citizens in the late 1980s and early 1990s; the rise of the religious right as a powerful political presence in the state and national political arenas; and, the election of a centrist Democrat, Bill Clinton, as President. This transformation of public attitudes toward conservative themes of limited government increased fiscal accountability and devolution of authority from the Federal government to the states and paralleled the rise in popularity of the reinvention paradigm.

Third, American business was beginning the longest running bull stock market in American history, and Americans were witnessing the seemingly overnight phenomenal economic success of high-tech start-ups, which made young inventors and investors millionaires many times over. The business sector came to be viewed as the “place with all the answers” in a fast-changing world.

EXAMPLES OF REINVENTION EFFORTS IN STATE GOVERNMENTS

Along with reinvention theory, the 1990s brought increasing power and prominence to states in shaping the national agenda. The zenith of this state government movement may well prove in hindsight to have been the 1995 Republican Congress “Contract for America,” in seeking to turn the federal social programs back to the state. There is great variation among states in constitutional structure, resulting in differences in service delivery design and implementation. These differences make it difficult to generalize how reinvention has impacted states. Recent research as well as national initiatives such as welfare reform

and the implementation of the Children's Health Insurance program, however, provide some glimpses of how reinvention has penetrated the structure of state government.

At the beginning of the 1990s, many states undertook studies to determine how reinvention principles might be applied. The most well-known effort to implement suggested reinvention reforms was Minnesota's redesign of its Department of Administration, as chronicled in *Breaking Through Bureaucracy*.^[13] Research at the end of the 1990s suggests that many states have taken major steps to redesign their basic administrative units with a focus on human resources.^[14] The emerging research suggests that states are using reinvention principles with new computer technologies to streamline human resource processes. Many states are delegating authority for personnel functions to agencies and managers, shifting human resource missions to focus more on collaboration with agencies, and adopting performance management systems.^[14]

Osborne and Gaebler^[1] provided numerous examples of potential modifications of the welfare and Medicaid systems. The Winter Commission^[6] echoed the need for change in these areas, with particular emphasis on Medicaid. Former President Clinton and Congress addressed these requests for change through two major federal initiatives that essentially devolved authority for federal programs to state level. These initiatives were national welfare reform in 1996 and creation of the State Children's Health Insurance Program (SCHIP) by Congress in 1997.

Welfare reform was enacted with the passage of the Temporary Aid for Needy Families block grant (TANF). TANF represented a transfer of responsibility for welfare design from the federal to the state level and a major shift in this country's low-income safety net. Aid to Families with Dependent Children (AFDC), an ongoing cash entitlement program with federal eligibility rules, was transformed into a capped, block grant allowing states to design and implement a time-limited work program. States were given broad flexibility in the design of their respective welfare programs as long as federal work participation rates, reduced welfare caseloads, and increased participants' earnings were met. States have taken the opportunity to re-craft their programs into broad-based, workforce programs using a myriad of private contractors to provide various employment programs in combination with social supports such as transportation and day care. State efforts combined with a strong economy have resulted in large reductions in welfare caseloads along with substantial increases in the number of former welfare recipients who are working.^[15]

SCHIP was created as part of Congress's effort to delink Medicaid from welfare. SCHIP provides states

the opportunity to enroll children with family incomes up to 200% of poverty level in Medicaid, and, in turn, receive a favorable matching rate of 80% federal funds and 20% state funds to insure this population. SCHIP also allowed parents of children to be enrolled in innovative state-designed insurance programs. The original SCHIP legislation also provided some flexibility in program design, which included limited cost sharing by recipients, simplified applications, and annualized enrollment. All of these changes reflect the customer and real-world service delivery emphasis of the reinvention movement.

Enacting the SCHIP program was clearly an effort by Congress to address the growing numbers of uninsured in this country. A number of states, such as Wisconsin, New York, Texas, Florida, Vermont, and Minnesota, have been able to use the new flexibility in the program to further expand coverage to uninsured children and families.

Newly elected President Bush chose Governor Tommy Thompson of Wisconsin to be his cabinet head of the federal Department of Health and Human Services (DHHS) in the winter of 2000. As Wisconsin's governor, Thompson was one of the leaders in state welfare and Medicaid reform. As Secretary of the Department of Health and Human Services, Thompson announced in the spring of 2001 further efforts by DHHS to allow states flexibility in SCHIP program design and, thus, encourage expanded state coverage to the uninsured.

With the start of the new millennium, a clearer picture is developing with regard to the impact of reinvention on state government. Most states have made internal efforts to streamline administrative processes. But, possibly more important in terms of fundamental state services, the federal government has wholeheartedly endorsed concepts of decentralizing services to the states, providing more flexibility, and monitoring results based on measurable outcomes and targets rather than enforcing standardized processes. These changes are core values of the reinventionists, and when enacted on the federal level, have fundamentally changed the work of state health and human services agencies. Even with the economy starting to downturn in the middle of 2001, there are no current political discussions of revisiting this fundamental transformation in service delivery in these areas.

CONCLUSION

On September 11, 2001, the United States experienced the worst terrorist attack on its own soil in its history. Three commercial airlines manned by terrorists crashed into the twin towers of the World Trade Center and the Pentagon causing thousands of deaths. A fourth

airline crashed into a field in Pennsylvania. As a result of these attacks, the federal government is substantially increasing its role in public protection at U.S. airports, along coastlines, water systems, dams, power plants, and other potential terrorist sites.

An unexpected result of this terrible tragedy has been that Americans have rapidly come to accept the need for government and have developed a newfound respect for government employees from firemen to policemen, to military officers, and to national leaders. As the economy plummets in the wake of these events, the federal government under a conservative administration is initiating not only a "War on Terrorism" but also an economic stimulus package.

This article began with an examination of social and political history in the 1990s that resulted in a large group of government leaders and the public who were willing to accept "reinvention" tenets and implement those tenets into government practice. The millennium brings a new confluence of variables which suggests that, while reinvention strategies have been successfully enacted in federal and state governments, U.S. citizens are even more willing now than they were to debate the "appropriate" role of government in providing public goods and public protection today.

Paul J. Brennan

Department of Accounting, Austin Peay State University, Clarksville, Tennessee, U.S.A.

INTRODUCTION

Public administrators use probability theory to account for uncertainty in many aspects of the policy process, especially the important functions of project planning and decision making. When engaged in project planning, public administrators employ probability theory to establish the likelihood of events that effect the allocation of scarce public resources. As a decision-making tool, probability theory is used in many techniques of policy analysis, especially when administrators are called upon to assess the expected benefits of alternative courses of action. Furthermore, probability theory is used to make inferences about the characteristics of a city, state, or nation's population and the presence of relationships important to the administration of public programs.

BASIC PRINCIPLES OF PROBABILITY

The fundamental principle of classical probability provides that the likelihood of an event is equal to the frequency of its occurrence divided by the frequency of all possible outcomes. For example, if each of 12 horses has an equal chance of winning a race, the probability that any one horse will win is 0.083 (1/12). In the same way, the probability of drawing a queen from a standard deck of 52 playing cards is equal to 0.077 (4/52). Moreover, the probability of any event lays somewhere between the values of 0 and 1. The total probability of all events is 1. An event that is certain to occur has a probability of occurrence equal to 1. Events that are certain not to occur have a probability of occurrence equal to 0. Although important theoretically, events that are either certain to occur or certain not to occur require no reference to the concept of probability.

It is important to note that probability theory is a key source of probability expectations in statistics. The examples of the horse race and the drawing from a standard deck of playing cards demonstrate that, although theoretically derived, probability expectations in statistics may also be gathered through

empirical experience (i.e., observation of “real world” events). Even the notion of subjective probability—probability established by the hunch of an expert—is founded in empirical evidence because the expert's hunch is based on past experience, even if the expert has never bothered to precisely quantify that hunch. Thus, a full appreciation of probability expectations in statistics is derived from both the implications of probability theory and the insights gained from everyday experience.

When estimating the likelihood of uncertain events, public administrators and policy analysts consider the related and important concepts of independence and conditional probability. Conditional probability refers to the likelihood that one event will occur contingent upon the occurrence of another event. The concept of conditional probability is related in the following example. Consider the hypothetical data presented in [Table 1](#). Assume these data reflect the outcome of a survey presented to the Democratic and Republican party members of a state legislature. Suppose that each respondent was asked to register an “agree” or “disagree” response to a policy proposal.

Table 1 reflects that of the 300 legislators surveyed, 90 issued an “agree” response and 210 indicated that they “disagreed” with the proposed policy change. Further, Table 1 reveals that of the 300 legislators surveyed, 200 identified themselves as Republicans and 100 indicated that they were members of the Democratic party. Most important, Table 1 indicates that the probability of selecting a legislator that “agrees” with the policy proposal from the list of Republican identifiers is equal to 0.30 (60/200). The likelihood of this event given the known existence of another event is known as its conditional probability. If two events are related, knowing conditional probabilities allows a policy maker to better predict a situation from prior knowledge of a related event.

Statistical independence implies that the probability that one event has occurred does not influence the probability that a second event will occur. If two events are independent, they are unrelated and knowing that one is present does not help a policy maker predict the likelihood of the other event occurring. Expressed

Table 1 Relationship between party membership and issue position

Party	Agree	Disagree	Totals
Republican	60	140	200
Democrat	30	70	100
Totals	90	210	300

mathematically, two events are statistically independent if the probability that both events occur is the product of their individual probabilities.

STATISTICAL INFERENCE: WORKING WITH SAMPLES AND POPULATIONS

The principles of probability outlined above are essential to the practice of statistical inference. As Anderson and Zelditch explained, probability is “the mathematical domain out of which virtually all statistical inference has emerged.”^[1] Statistical inference is used for making decisions for a wider population based on observations of a sample. A sample refers to a small subset of a population. When engaging in statistical analysis, social scientists typically examine the characteristics of a sample. Known as statistics or estimates, these characteristics are used as substitutes for the typically unknown, if not unknowable, qualities of the population (called parameters). When using estimates to make inferences about the characteristics of a population, social scientists prefer to gather probability samples. Welch and Comer related that, “In a probability sample, every object or unit of population has a known probability of appearing in the sample.” In addition, the authors explained that use of a probability sample “allows you to judge how well sample results reflect the population.”^[2] Moreover, knowledge of the “fit” between a sample and its population is the foundation of all exercises in statistical inference.

Statistical inference is used by social scientists because it allows for reliable, educated guesses regarding the characteristics of a population in the absence of an ability to examine all units that comprise the population. In addition, probability theory is closely linked to the concept of statistical inference in that social scientists are frequently called upon to draw tentative, yet reliable conclusions regarding relationships among elements that comprise a population. In short, statistical inference allows social scientists to draw these tentative conclusions and express, using the basic features of probability theory, the likelihood of an erroneous conclusion. Applications of probability theory and the related logic of statistical inference allow public administrators and other social scientists to make decisions with a known degree of confidence.

Specifically, then, how might a public administrator use probability theory and the logic of statistical inference to answer a practical question? Suppose public officials in a large community want to market services to the local population in the most cost-effective way. In addition, suppose they want to conduct a survey to test their suspicion that older residents in the community demonstrate a higher propensity to use city-owned recreational facilities. Yet, polling all residents of a large community would be either unduly burdensome or prohibitively expensive. What is a public manager to do? The answer involves gathering a representative sample of community residents, measuring their ages and tastes in recreational facilities, and using statistical inference to draw tentative, though accurate, estimates of the relationship between these two variables in the entire population.

The capacity to draw these conclusions is rooted in the concept of a probability distribution. If a large number of repeated samples are drawn from a population and if a particular characteristic is measured from each sample, a distribution of these measures—known as a probability distribution—emerges. This particular form of probability distribution is known as a sampling distribution. If policy makers understand the behavior of the sampling distribution, they may apply rules of probability to estimate a range of outcomes. In short, within a probability distribution, the likelihood of any particular value occurring may be reliably determined. Thus, public administrators are able to discern how likely it is that a particular result will occur merely by chance.

All sampling distributions are defined by two key features—their mean, or arithmetic averages, and standard deviation. The standard deviation refers to the average amount of variation of values in a group of data vis-à-vis the mean of the group of data. In other words, all else being equal, distributions with large, as opposed to small, standard deviations are characterized by a high degree of dispersion of values around the mean. By contrast, all else being equal, distributions with small standard deviations are said to reflect a high density of values immediately around the mean of the distribution. Thus, assuming equivalent means, any two distributions will vary in apparent “shape” to the extent that their standard deviations are unequal.

THE IMPORTANCE OF THE NORMAL PROBABILITY DISTRIBUTION

A basic understanding of probability theory and its applications requires familiarity with the idea of the normal probability distribution and the Central Limit Theorem. The importance of the normal probability

distribution in statistical inference is derived from the Central Limit Theorem. This theorem provides that the means drawn from repeated random samples of a population will follow a particular pattern, known as a normal probability distribution, provided that the sample sizes are sufficiently large. Considering the nature of a sampling distribution and the dictates of the Central Limit Theorem, as the number of repeated samples in a distribution increases, the “shape” or basic features of the sampling distribution closely resembles those of the population.

The Central Limit Theorem also dictates that, as the number of samples increases, the distribution of sample means will follow what is known as a normal distribution.^[3] When depicted graphically, the normal distribution takes on the familiar shape of the symmetrical, bell-shaped curve possessing a single mode. The particular case of the distribution of sample means reflects a distribution with a mean equal to the population mean and a standard deviation equal to the standard error of the mean (population standard deviation divided by the square root of the sample size). It is important that the Central Limit Theorem will hold regardless of the shape of the underlying population, but the samples drawn from populations departing substantially from normality will require larger sizes before the means of the samples can be assured to follow a normal distribution.

The Central Limit Theorem is the foundation of all exercises in statistical inference. Further, it is the reason why the normal probability distribution is so often used in inferential statistics. Yet, much data in the world does not follow a normal probability distribution and unless one knows something about the underlying characteristics of a probability distribution, one cannot predict the probability of getting a certain occurrence in a range of occurrences. Fortunately, the Central Limit Theorem tells us that, even if the underlying population is not normally distributed, means from repeated samples will follow a normal distribution provided that the sample size is sufficiently large. Armed with a sample mean and an estimate of the standard error of the mean, one can make a prediction about the population mean and the probability of obtaining a given sample mean from that population. This condition holds due to fact that the sample means will follow a normal probability distribution with a mean equal to the population mean and a standard deviation equal to the standard error of the mean. In addition to the sample mean, other sample statistics follow normal probability distributions or closely related distributions, such as the t distribution.

Often, researchers want to estimate, with a known measure of confidence, a particular characteristic of a population. Beyond the Central Limit Theorem, an additional concept, the principle of large samples, is

of particular importance to students of probability theory. An example illustrates this point most effectively. Suppose we wanted to know the average age of all citizens of China. In our effort to do so, we might compile a list of the ages of 10,000 randomly selected Chinese citizens. After calculating the average age of these 10,000 persons, can we use this number as our estimate of the average age of the population of China? Considering that our sample is very large, the answer is yes. The principle of large samples tells us that as sample size increases, our estimates derived from those samples more closely resemble the true population characteristics or parameters. Despite this, our confidence in the accuracy of this estimate is still an open question. What might we do to enhance our confidence in the accuracy of our estimate?

One strategy for increasing our confidence in the accuracy of our estimate is to conduct repeated sampling procedures and, on each occasion, identify the average age of persons in each sample. Based on our discussion of the Central Limit Theorem, if a large number of samples are gathered and sample averages calculated, a distribution of these sample averages could be formed. If that distribution were presented graphically, it would resemble a bell-shaped curve or what statisticians refer to as a normal curve. The peak of this distribution indicates the value calculated most frequently in the repeated samples. This value is known as an estimate, or a “good guess” as to the average age of the entire population. In short, as repeated samples are conducted, the value of our estimate approaches the value of the average that would result if we were able to examine the entire population.

PROBABILITY THEORY AND CONFIDENCE INTERVALS

The lessons of probability theory are especially important when constructing confidence intervals from statistical estimates. A confidence interval is a probability boundary for a population parameter estimated from a sample. Furthermore, Manheim and Rich describe a confidence interval as “an indicator of the accuracy with which a population parameter can be predicted from a sample statistic stated in terms of the range of values above or below the sample statistic the population parameter is likely to fall.”^[4] Many types of confidence intervals can be estimated from a sample. A confidence interval may be estimated for a population mean, a difference between means, a population proportion, a difference between population proportions, a population variance, a population standard deviation, a difference between two population standard deviations, a correlation coefficient, or a regression coefficient. This list is not exhaustive.

Confidence refers to the degree of certainty that the estimated interval contains the population parameter. Confidence refers to the degree of certainty that a certain percentage of similar statistics from repeated samples would fall within the interval. This is nearly the same as saying that, within a certain specified probability, the population parameter would fall within this interval. Confidence intervals are generally two-sided and constructed as follows:

$$V \pm Z(SE)$$

where V = the value of the statistic computed from the sample; Z = the value of the multiplier for a stated probability level obtained from a probability distribution; and SE = the standard error of the estimate.

The following example reflects the application of probability theory to the concept of confidence intervals. Suppose the director of the parks and recreation department of a large municipality decides to perform a survey to discover whether a proposal for expanded hours for the municipality's indoor recreation facilities is justified by community demand. The administrator plans to propose additional evening and weekend hours, but the expanded hours will require additional staffing and facilities expenses. The administrator decides to survey regular or occasional users of the facilities. The administrator will make the proposal if it is believed that at least 30% of facilities users indicate that they would at least be "quite likely" use the facilities during the proposed new hours.

The administrator's population of interest is users of the city's indoor recreation facilities. The director has made the decision to ignore non-users by assuming that increased hours will not have a significant impact on their behavior. The administrator wants to have some idea of whether expanded hours can be justified by increased demand. Because of time constraints, the administrator is not able to survey all users but chooses a sample of users instead. Based on the sample information, the administrator will infer the level of demand in the overall population.

Assume that a sample of 200 users is obtained. Those responding to the survey are asked how likely they would be to use the facility during the expanded night and weekend hours. The question is answered on a 5-point scale with scores of 4 and 5 representing respective choices of "quite likely" and "extremely likely." Thirty-seven percent of the users answering the survey fall into those two categories.

Based on the survey evidence, may the administrator infer that at least 30% of users would use the facility during expanded hours? The administrator must employ probability theory to test these hypotheses and estimate a confidence interval for the expected percentages in the overall municipal population.

Suppose the administrator uses the confidence interval approach to estimate a population proportion. We know that sample proportions will vary randomly around the true population proportion from sample to sample. Sample proportions of this type may be modeled as random variables following a binomial probability distribution. The normal distribution may also be used to approximate the binomial distribution of sample proportions from this population of samples.

Most likely, the director would use a computer statistical package to estimate the confidence interval of the population proportion from the sample estimate. Assume that a 95% confidence interval is chosen by the director as an adequate level of statistical confidence to estimate the population proportion. If the confidence interval includes values less than 30%, the director will be unable to conclude within the desired level of confidence that more than 30% of the overall user population will be "very likely" to use the facilities during expanded hours. However, if the confidence interval does not include values less than 30%, the director will infer that the demand level in the overall population is met.

The obtained 95% confidence interval using the exact binomial probability distribution is (0.276, 0.472). Although the confidence interval includes estimates of the population proportion well in excess of the 30% demand-level target, the interval also includes estimated values less than 30%. The administrator cannot conclude within the desired level of confidence that the demand level in the population is greater than 30%. In fact, the demand level could be as low as 27.6% and one could obtain a sample proportion as high as 37% from a sample of 100 with a small, but not extremely unlikely frequency.

Note that the confidence interval obtained in our example is rather large (almost twenty percentage points). The director could obtain a narrower confidence interval by either sampling a larger number of individuals or choosing a lower level of confidence. The obtained confidence interval if the sample is expanded to 200 individuals and the same proportion of 37% fall into the top two categories of responses is (0.303, 0.441). Here, the lower bound of the confidence interval exceeds the target figure, and the director may be confident that sufficient demand exists in the user community. If a 90% confidence interval had been chosen for the sample of 100, the estimated interval would be (0.289, 0.457). Choosing the later alternative is easier but does not shorten the confidence interval as much and still does not allow the director to conclude that the population demand is in excess of 30%. In addition, choosing a lower level of confidence increases the researcher's chances of making a mistake in inferring a population proportion from a sample estimate.

CONCLUSION

Probability theory is the foundation of statistical inference, a necessary process to decision making in public policy. Statistical inference requires knowledge of a set of concepts and tools springing from probability theory, including an understanding of the normal probability distribution, other important probability distributions, the concepts of hypothesis testing, and construction of confidence intervals for estimates of population parameters. Public administrators use all these basic concepts when engaging in scholarly pursuits and making resources allocation decisions. The application of probability theory has played a central role in modern and contemporary efforts to rationalize the tasks of governing. Probability theory is, and

will remain, an important source of guiding principles in the study and practice of administration.

Procurement

Charles K. Coe

*Department of Political Science and Public Administration, North Carolina State University,
Raleigh, North Carolina, U.S.A.*

INTRODUCTION

State and local governments annually purchase over \$850 billion of goods and services. Because of the large sums involved, procurement is a fundamental aspect of governmental operations. Professional policies and procedures reduce costs; conversely, shoddy practices cause waste and excessive costs. Well-managed procurement programs should be soundly grounded with laws, regulations, and ethical standards; professionally acquire goods and services; securely operate a fixed-asset system; follow sound inventory control and management procedures; and be regularly evaluated. Let us discuss each requisite.

A SOUND FOUNDATION

A purchasing materials management program must have a sound foundation that includes well-trained personnel; laws and regulations adhering to federal government directives, basic contract law, the Uniform Commercial Code, state law, and local ordinances; a system centralized in a single office; an operating manual; and clearly defined ethical standards. Governments should inform the public and vendors about their policies and procedures in writing and on their website.

State laws direct most, if not all in some states, procedures that local jurisdictions must follow in purchasing goods and services. Purchasing officers should, therefore, be intimately familiar with their state's requirements, paying particular attention to provisions covering acceptance of bids and proposals, preparing specifications, advertising of the letting of contracts, withdrawing bids, and executing contracts.

The American Bar Association has published two guides for preparing a local purchasing ordinance or code: *The Model Procurement Code for State and Local Government* and *The Model Code for Local Governments* that is intended to meet the needs of smaller governments.

ROUTINE PURCHASING

Most goods purchased follow the basic purchasing cycle that includes preparing a purchase requisition;

determining if bids are required, and if so, preparing an invitation for bids; evaluating and awarding bids; preparing and administering a purchase order; receiving goods; making payment; and evaluating vendors' performance. Contracts are awarded to the lowest responsible and responsive bidder. A "responsible" bidder must be able to perform the contract specifications, meeting the material terms of the invitation for bids. Accordingly, bids are usually awarded to the lowest bidder. The predictability of the normal purchasing system may give policy makers the false impression everything works smoothly. To the contrary, the purchasing system, like any other system, can always be improved.

In particular, administrators should vigilantly evaluate bids and purchase orders for their completeness; guard against unwarranted changes proposed by vendors; and carefully inspect delivered goods to insure that they meet contractual requirements. After a vendor has received a specified number of complaints, the government should take corrective action.

The purchase description, called a specification, is at the heart of the procurement process, informing the vendor what is required and providing the basis for awarding the purchase order or contract. The purchasing office prepares most specifications; however, agencies may take the initiative. In this case, the purchasing office should reserve the right to review specifications that the agency prepares. Purchasing officials should avail themselves of all resources in preparing specifications. National and professional societies have standards for some commodities. Likewise, federal, state, and local governments have a wealth of expertise that is one call away. Other helpful sources for specification writing and purchasing are found in [Table 1](#).

Purchasing and materials management should be computerized if possible. To ensure that vendor bidding is competitive and track vendor performance, governments should register vendors in a database that maintains vendor financial data (such as tax status), tracks vendor performance, and is the basis for making payments. A contracting module generates bid lists, tracks purchase orders, and assists in preparing, awarding, and monitoring contracts.

The Internet likewise streamlines purchasing. Suppliers offer their catalogs on the Internet, governments send bid notices and solicitations electronically, and a

Table 1 Resources for purchasing assistance

Source	Address	State	Telephone
National Institute of Governmental Purchasing	11800 Sunrise Valley Drive, Suite 1050	Reston, VA	703/715-9400
National Purchasing Institute	7910 Woodmont Ave.	Bethesda, MD 20814	800/695-1025
National Association of Purchasing Management	2055 East Centennial Circle	Tempe, AZ 85284-1898	800/695-1025

wide variety of purchases are made online. The Internet increases the pool of bidders, while saving vendors and governments money by reducing transaction costs. Electronic commerce is paperless and integrates cataloging, ordering, and exchanging financial transactions.

Using the Internet, governments can find help to prepare specifications, understand recommended purchasing procedures, jointly purchase with other governments, and train purchasing officers. Particularly useful are the following websites:

- The National Association of State Purchasing Officials (www.naspo.org).^[1]
- The National Institute of Governmental Purchasing (www.nigp.org).^[2]
- The National Association of Purchasing Management (www.napm.org).^[3]
- The National Contract Management Association (www.ncmahq.org).^[4]
- Procurement “jump” sites (www.fedmarket.com/statejump.html#35).^[5]
- Federal Electronic Commerce Program (www.ec.fed.gov).^[6]

Similarly, using credit cards to purchase small items results in savings. To establish a credit card system, purchasing officers should first conduct a cost analysis to determine which situations and which price ranges warrant their use. Strict accounting controls should be enforced to avoid misuse. Credit card advantages include:

- Instead of paying scores of vendors, only one credit card company is paid.
- Payments are scheduled to optimize payment, thereby increasing the amount of time to invest funds.
- Most credit card companies provide up-to-date reporting and query capabilities, which are more accessible than most governmental accounting systems.

NON-ROUTINE PURCHASING

Purchases falling outside of the normal purchasing cycle include purchasing services, cooperatively purchasing with other governments, volume purchasing,

emergency purchasing, sole-source purchasing, petty cash fund purchasing, and environmental purchasing. Of these, the most challenging, technical, and complex is purchasing services, which is more complicated than routine purchasing for two reasons. First, contracts for services are awarded not principally on lowest cost but on firms’ experience. Second, some services are technical, and contracts for them must be negotiated. There are four types of services: professional services (e.g., legal), operating services (e.g., solid waste collection), technical services (e.g., MIS installation and software), management services (e.g., motor equipment maintenance and repair), and client services (e.g., halfway houses and counseling). Defining the scope of technical services, such as legal, engineering, management information service (MIS) software and hardware installation, and auditing, is challenging. For more technical services, a work team—typically comprised of the contract manager, a departmental representative, and representatives from purchasing, budget, and legal—prepares the scope of work specifying the contractor’s and government’s responsibilities and general contractual conditions including payment procedures, insurance requirements, and bonding requirements. Contracts are then negotiated and require careful governmental oversight.

Looking at other non-routine types of purchasing, cooperatively purchasing with other governments saves money due to larger economies of scale. There are three types of cooperative purchasing: two local units joining together to purchase a good or service (e.g., a city jointly purchasing cleaning supplies with a school system); a joint association of two or more governmental units (e.g., all states permit local units to purchase goods on their state contracts); and a new legal entity, such as a regional purchasing council. Volume purchasing is made for repeated purchases. Rather than repeatedly issue purchase orders, one purchase order for an item is issued for a specified period, thereby reducing costs and eliminating inventories. Sole-source purchasing should only be done after a good faith review determining that only one source is available. Reasons for sole-source purchases should be documented in writing. A petty cash fund for small amounts, typically from \$10 to \$100, eliminates purchase orders, thereby saving time and money. Petty

cash funds need strict accounting controls, ironically, because of the small amounts involved, which sometimes cause employees to forget to account properly for withdrawals. Finally, governments should make environmentally responsible purchasing decisions, including, where cost effective, buying recycled products, setting recycling content standards for paper and paper products, not buying disposable products, not buying batteries or other mercury-containing products when alternatives are available, purchasing energy-efficient lightbulbs and fixtures, and buying non-toxic, biodegradable cleaning products.

FIXED-ASSET INVENTORY SYSTEMS

A fixed-asset inventory system that maintains accounting controls over buildings, land, and equipment is a useful capital planning tool, stops tools and equipment from “walking” off with employees, and informs managers about the amount of capital that should be protected (through insurance or self-insurance) against risks of theft, fire, or vandalism. A fixed asset has a useful life of at least one year. The government must decide the capitalization limit, which is the dollar limit over which fixed assets must be accounted for and recorded. Two competing considerations govern the decision: 1) the higher the limit, the fewer the assets, and the less cost of creating and maintaining the system; but 2) the less accounting control is exercised.

The Governmental Accounting Standards Board (GASB) Cod. states that fixed assets should be valued at their initial cost (Cod. Section 1400). However, in creating a system, governments likely have fixed assets with no record of their initial costs. In which case, GASB permits using estimated historical costs. Next, the government should form and train a team to conduct the initial inventory, tagging physical assets and accounting for depreciation. Facility assets should be depreciated on a composite straight-line basis at a 2% annual rate. Other assets should be depreciated at the following rates: furniture and office equipment (10%); maintenance and construction equipment (12%); medium and heavy motor vehicles (30%); and data-processing equipment (20%). Finally, the government should fix personal responsibility for assets, prescreening purchases to see if they are fixed assets, and following procedures for additions, changes, and disposals.

INVENTORY CONTROL SYSTEMS

Whether to have an inventory is a benefit–cost decision. Keeping supplies and equipment in an inventory reduces downtime to get parts, decreases theft due to having accounting control, decreases the paperwork of making numerous purchases, and can give

management information about the costs of supplies on particular jobs. On the other hand, inventories have costs including staffing the facility, carrying costs including obsolescence and deterioration, investment interest lost due to goods tied up in inventory, insurance costs, and equipment (e.g., forklifts, shelves, and pallets).

When costs exceed benefits, governments should instead volume purchase using blanket contracts. If benefits exceed costs, creating a system entails fixing responsibility for creating and operating the system, deciding what to stock, deciding how to stock (e.g., two bins, periodic inventory, perpetual inventory), purchasing software, adopting a commodity classification code identifying items and cross-referencing them against manufacturers’ parts numbers and the user’s parts numbers, designing a stores plan, and adopting an inventory procedures manual.

EVALUATING THE PURCHASING PROGRAM

The purchasing manager should routinely evaluate the effectiveness of the purchasing program. The customers of a purchasing department are the operating departments. Accordingly, the purchasing departments should regularly survey them to assess satisfaction levels and solicit recommendations for improvement. Likewise, purchasing agents should annually conduct customer satisfaction surveys with a representative sample of vendors who do business with the government. Agencies and vendors are concerned with the amount of time taken from the time of the requisition to the time of awarding a contract or completing a purchase order. Efficient purchasing departments should be able to issue routine purchase orders in a matter of a few days. Contracts requiring formal bids take more time, of course.

Productivity and Effectiveness

Patria de Lancer Julnes

Department of Political Science, Utah State University, Logan, Utah, U.S.A.

INTRODUCTION

Productivity and effectiveness are important concepts for public administrators. However, there seems to be no agreed-upon definition of the terms or clarity of the relationship between them. These issues are addressed here. In addition, this article includes discussions of the history of productivity improvement efforts, the measurement of productivity, and some strategies for improving productivity.

DEFINING PUBLIC PRODUCTIVITY AND EFFECTIVENESS

Productivity

Although the concern for productivity has a long-standing tradition, there has been some ambiguity as to what it means. According to standard usage, productivity refers to the level of output—amount of services delivered, given a certain level of inputs. Defined this way, productivity is calculated as a ratio that attempts to answer the more general question: how well are resources used? If an agency increases outputs without requiring more inputs or if it maintains the same level of outputs after reducing inputs, then that agency has increased its productivity. Economists call this technical efficiency.

However, this simple definition of productivity does not capture all the nuances of common usage of productivity as applied to producing an output or delivering a service. Productivity is affected by many issues; accordingly, this has made it necessary to find different ways of thinking about it. For example, some think of public service productivity not as a simple ratio but as the responsiveness to the needs, desires, and resources of the community.^[1] This emphasis on responsiveness starts to overlap with effectiveness, the other topic discussed in this article.

Effectiveness

The term “effectiveness” has been emphasized by those interested in more than technical efficiency—not just outputs, but desired outcomes. In common parlance, effectiveness in the public sector refers to the

overall impact and outcome of policies or programs. An effective program achieves the desired outcomes, which typically follow from the program’s mission, goals, and objectives without creating other problems. This definition implies causality, and some argue that assessing something as abstract as a causal relationship is outside the realm of the day-to-day monitoring of operations of an agency. Given this concern, a definition of effectiveness that has been argued to be more appropriate for public productivity is implementation effectiveness, which refers to the extent a program is implemented in a way that produces and delivers the *right* amount and quality of services.^[2] Others have gone further, defining an agency’s effectiveness in terms of the relationship between internal processes and mission achievement. They argued that an agency is effective if it “does well that which it is supposed to do, whether people in the agency work hard and well, whether the actions and procedures of the agency and its members are well suited to achieving its mission, and whether the agency actually achieves its mission.”^[3]

The emphasis on effectiveness is an important contribution to the field of public productivity. But note that, as with productivity, the term effectiveness also has some ambiguities. Although some define it in terms of outcomes and impacts, others argue for output- and process-based definitions.

Linkage Between the Two

In focusing on output and quality, implementation effectiveness provides a complementary answer to the question of the extent to which resources are being used appropriately. For example, if an agency becomes more productive—that is, delivers more services (output) on a weekly basis with the same number of case workers (input)—but does so at the expense of quality and poorly completed paper work, this is not a good outcome and thus resources are not being used well. This dictates that the managers need to pay attention to the process.

Consider the following question as a second example. What does an increase in the number of arrests (outputs) by officers in a police precinct tell us about the success of a newly implemented productivity improvement program (e.g., a new promotion system)? Based on these numbers alone, one would

conclude that the productivity-enhancing system is good and effective in motivating the police officers to work harder. However, what if one consequence of the policy is that innocent citizens are being arrested? This will decrease the conviction rate and decrease citizens' confidence of the police. In such scenario, this productivity-enhancing program is not effective. This is a simplistic example, but it helps to illustrate that even if productivity is increased without compromising the quality of arrests, for example, one needs to know that there is not a negative impact on society. Thus, focusing on output, quality, or technical efficiency alone is not enough. Productivity and effectiveness must go hand in hand. However, as discussed in the next section, this conceptual partnership has proved problematic.

THE PRODUCTIVITY MOVEMENT

At its inception as a field, the study of public productivity was based on a rational/technocratic approach emphasizing technical efficiency. The study of public productivity has been traced back to an interest in efficiency as the vehicle to wealth.^[4] Since the 1800s, public and private productivity have been quantified in the United States, but more attention has been paid to productivity since World War II. In the United States, an increased interest in efficiency in the public sector was stressed in 1887, when, in his seminal essay, Woodrow Wilson supported a civil service reform that emphasized professionalism in public administration to change the corrupt behavior of public officials.^[5] Although not directly emphasizing efficiency, the belief at the time was that politics had to be separated from administration because the intervention of politics inhibited good administration. Political immorality precluded the development of a professional, accountable, and well-trained public administration, which, in turn, led to inefficient public administration.

Such ideas served as the foundation of a desire for "good" government, and the adoption of administrative practices with procedures and measurement techniques to identify and increase the productivity of workers. From the late 1800s to 1940, economists used productivity to describe the link between resources and products; however, efficiency and economy were more popular terms. The comparison of inputs to outputs is the basis of applications such as scientific management.^[6] Nonetheless, this emphasis on efficiency was questioned by many because it did not pay enough attention to satisfaction or the benefits or results produced.^[7] That is, the definition of efficiency as the accomplishment of the work with the least expenditures of manpower and materials neglected the concept of effectiveness, or allocative efficiency, as it is known in the economics literature.

From the 1940s to the 1970s, the period Bouckaert called "government by administrators," the focus of government was to control expenses through the budget process.^[7] Although productivity, doing more with less, remained of interest, improving decision making through the application of positivist, scientific techniques were the goal.^[2] It was during this era that the planning programming budgeting system and zero base budgeting were developed, and suggested for adoption throughout government.

Furthermore, in 1962 numerous studies were commissioned under the Bureau of the Budget to assess the feasibility and usefulness of productivity measurement. But nothing was implemented until after the 1970s.^[7] Effectiveness, and particularly institutional effectiveness, became a core value in the field of public administration because of the work of leading scholars of this period.^[8]

In the 20-year span between 1970 and 1990, triggered by the growth and cost of government programs and general problems in the economy, a heightened cynicism on the part of the public toward government led to the development of measures of public productivity and appropriate techniques for improving it. As explained by Schein, the public became cynical about the money spent by public organizations on social services; tax dollars spent did not seem to be providing an appropriate level of return as judged by the apparent failure of programs to solve social problems.^[9] Improving government productivity—more yield per dollar spent—became the mantra.

In 1970, under President Nixon, the National Commission on Productivity was created (later changed to National Center for Productivity and Quality of Working Life). One of the goals of this commission was to improve government productivity. Similar efforts followed at the state and local levels. Academia also contributed to the productivity improvement effort. One of the most recognized leaders in the field is Marc Holzer who in 1972 created the National Center for Public Productivity, NCPP (<http://www.ncpp.us/index.php>). The NCPP contributes to the improvement of productivity in the public sector through research and public service. Two major publications of the center include the journal *Public Performance and Management Review*, and the *Public Productivity Handbook* (1st and 2nd editions).

Government productivity improvement efforts of the 1970s were followed by somewhat opposite efforts with similar goals, increasing efficiency by reducing government's involvement in delivering services. This reduction was believed to be best accomplished through privatization and the contracting out of government functions. The assumption was that the private sector could do a better job than the public sector and still deliver services at a lower cost. At

the same time, public administration scholars became more concerned with the ethical, legal, and economic constraints on government. Effectiveness per se was folded in these three issues.

Embedded in the assumption held by many Americans that a large portion of public funds are wasted^[10] while the private sector continues to improve quality, initiatives to improve public productivity now focus on increasing constituents' satisfaction with the way tasks are performed.^[11] The period beginning in the 1990s has seen an expansion of the meaning of productivity to include such things as results or outcomes and quality of services. Governments now attempt to show their constituents what they are getting for their tax dollars, how efficiently and effectively their tax dollars are spent, and how expenditures benefit their lives.^[12] Performance measurement has been touted as the vehicle for accomplishing these public goals.

MEASUREMENT AND PRODUCTIVITY

At the core of productivity improvement is performance measurement. The basic reason for conducting performance measurement is to strengthen government's resource allocation and administrative decision-making capabilities.^[13] The importance of performance measures derives from their empirical basis for decision making.^[4] Measures of productivity can be used to maintain internal and external accountability; to provide a rationale for the development of goals and objectives, resource allocation, and monitoring results; and to support modifying plans to enhance performance.^[1,14]

Because performance measurement is considered an important aspect of governmental management, several organizations including the Governmental Accounting Standards Board (GASB), the National Academy of Public Administration, and the International City Managers Association, are encouraging and working with governments to experiment with them.^[15] Notwithstanding these efforts, establishing a performance measurement system often faces a wide range of obstacles, ranging from individuals' resistance to measurement to an organization's lack of technical or analytical skills.^[16]

Furthermore, the establishment of a performance measurement system can have serious drawbacks if it is not done properly. In particular, a system is not good if it does not provide appropriate information to decision makers, and it can hurt an organization if it misrepresents, misleads, or introduces perverse behavioral incentives.^[13]

The GASB has suggested that public organizations assess performance in ways that go beyond the relationship of outputs to inputs. It recommends that organizations use various measures including those

that relate their efforts to their accomplishments. The GASB adds to the measures of inputs (amount of resources used) and outputs (amount of workload accomplished) measures of outcome and efficiency.

STRATEGIES FOR IMPROVING PRODUCTIVITY

The amount of available resources and their effective use have been central concerns in productivity improvement efforts. However, if public organizations are to improve their productivity as defined in the broader sense, they need to employ a management framework that allows them to develop and reinforce their production capacity. In discussing award-winning government agencies, Holzer and Callahan concluded that these organizations tended to^[12]

- 1) apply quality management principles; 2) use measurement as a decision-making tool; 3) invest in human resource development and organizational learning; 4) adapt new technologies; and 5) develop partnerships with the private sector, with other governmental and non-profit agencies, and between management and labor.

These recommendations appear reasonable; the question, then, is how to put such framework into practice? Rosen offered some specific guidelines for making productivity improvement decisions that come from lessons learned in practice.^[2] First, there is the realization that productivity improvement takes time. Therefore, strategies must be thought through thoroughly and carefully. Reforms should be kept simple, and projects that present the least risk but have high potential of success should be started with. Pilot projects should be conducted and evaluation should be ongoing. This, however, must be accompanied by a participative orientation and open communication. Second, it is important to anticipate resistance and to develop the appropriate strategies for dealing with it. Those strategies would include attaining top-level support, maintaining open discussions with stakeholders, and building rewards into the productivity improvement plan. Third, you have to choose a problem that most people see as a problem. Fourth, the solution must be the right solution in that it should be a proven approach to the problem. At the same time, it must be feasible and timely. Fifth, the goals must be clearly defined and method for measuring success devised. Finally, the productivity improvement program must be thought of in terms of its effect on the organization as a whole.

As highlighted above, productivity improvement efforts must be conducted in a systematic way. Approaches that have been successful elsewhere must

be adjusted to the local context. Also, it is important to recognize that productivity improvement must be a team effort. Productivity improvement efforts are more likely to succeed if they have the support from individuals at all levels of the organization, including elected officials.

CONCLUSION

Traditionally, productivity improvement efforts focused more on quantity (outputs) than on quality and impact. It's been argued here that such an approach is needlessly simplistic. To be more useful, productivity improvement efforts must also involve efforts to improve effectiveness. But as was discussed here, the practical and conceptual connection between productivity and effectiveness has been problematic. To overcome this impasse, it is recommended that organizations adopt a systematic managerial framework based on a broadened conceptualization of productivity that includes measures of effectiveness.

Program Budgeting (PPBS)

Katherine G. Willoughby

*Department of Public Administration and Urban Studies, Georgia State University,
Atlanta, Georgia, U.S.A.*

INTRODUCTION

Program budgeting is a reform of traditional budget practice that is based on a program structure and the systematic analysis of government goals and objectives in order to inform decision making. This method of budgeting requires that costs be associated with the conduct of agency activities, that alternatives to meeting program objectives are generated, and that a multiyear focus on program operations is instituted. Within a program budget framework, “budget material is arranged in such a way as to aid the executive and legislature in understanding the broader policy implications of their decisions.”^[1]

OVERVIEW

Program budgeting received heavy scrutiny in governments in the United States during the mid-twentieth century. It represented a dramatic departure from a traditional focus of budgeting on the objects of expenditure. That is, a program budget focuses on agency outputs and the results of government activities, while a line item budget focuses on the resources necessary for input to government operations. The planning orientation of program budgeting pushed managers and budgeters past traditional roles of prudent stewardship and efficient administration.

TERMINOLOGY

Program budgeting, or planning, programming, and budgeting system (PPBS), has unique characteristics that set it apart from prior budgeting approaches. These include a program versus functional budget structure that emphasizes a more comprehensive approach to understanding government activity. It is at the program category level that the broad goals of government are declared. Goals are distinguished from objectives as being more general—“a desired state of affairs based upon current knowledge and values” and thus timeless.^[2] For example, the goal of the education program as stated in the State of Pennsylvania 2001–2002 budget is “to provide a system of learning

experiences and opportunities that will permit each individual to achieve his or her maximum potential intellectual development.”^[3]

A tiered structure subdivides program categories into subcategories and then elements. Goals become more specific as programs are subdivided and as the mission becomes more directly actionable. By the subcategory or subprogram level, associated objectives require the quantification of program affects “within a given timeframe and employing available resources.”^[4] Whereas goals are idealized, representing a valutive and desired state of affairs, objectives are measurable and must be both realistic and achievable.

The program structure is the foundation for a system that requires strategic planning, a multiyear focus in budget preparation, information gathering, cost assessment, alternative generation, and reporting. Results from the analysis of programs as tiered is delineation of government activities presumably to foster better understanding of the linkages between program goals and objectives, resource input, and the results of government spending. Program budgeting is premised on the notion that systematic collection and analysis of information and reporting about what government does can enhance decision making about what government should do. This approach is a concerted effort to examine program impact (a good indicator of government effort) rather than program input (a less than satisfactory indicator of government effort). A program approach to budgeting that emphasizes the “measuring, monitoring, analyzing” and reporting of government operations helps to focus attention on program performance, outputs, and outcomes.^[5] The planning focus and systematic analysis require both administrators and budgeters to think beyond what happened last year, past an incremental perspective.

HISTORY

Although formal introduction of a program approach to federal budgeting was made with great fanfare in the 1960s, experience with this approach existed prior to that time by public and private sectors both here and abroad. Novick’s compilation of cases of program budgeting system applications and experiments

includes nine countries and the United States, two state governments, one local government, a school district, and two private companies.^[2] Explanations of local government applications with special reference to the Los Angeles and New York City experiences, and mention of efforts in Washington, DC, Dayton, Denver, Nashville, San Diego, Dade County, Florida, and Nassau County, New York, also exist.^[6] General Motors, then Ford, and finally Chrysler automobile companies experimented with program budgeting beginning in the 1920s. Case studies of use by General Electric and the John Hancock Life Insurance are also in evidence.^[2]

Certainly pressure from the progressive movement for more rational (*vis-à-vis* political) administration of public programs and activities underscored the need for system centralization, budget comprehensiveness, and information collection and analysis that is evidenced in a program budget approach. Scientific method, systems, and operations research also served as foundations for program budgeting analyses requirements, at least in ideal form. Early governmental influences to future program budgeting initiative at the federal level include the Taft Commission on Economy and Efficiency of 1912 (argued against a line item budget format) and the Budget and Accounting Act of 1921 (created the federal executive budget process, a central budget office, and analytical support via the General Accounting Office).

Government fiscal policy also influenced the budget reforms in this century with increasing spending and more complex administrative structures necessitating attention to the budget process. For example, federal spending jumped from \$7 billion in 1934 to \$91 billion by 1944. The Brownlow and Hoover Commissions in the 1930s and 1940s, the Reorganization Act of 1939, and the Budget and Accounting Procedures Act of 1950 reoriented government, arming it with a strengthened executive and more centralized budget process as well as advanced information and data-gathering requirements of public managers.

Early application of program budgeting at the federal level occurred first in military agencies, beginning with the Army in the 1950s, and then in the Department of Defense by 1961. The Johnson administration called for implementation of program budgeting in 25 civilian agencies by 1965. The focus of the initiative was to advance development of program missions and goals, subprogram objectives, and then information and data related to those subprograms and elements to provide systematic cost assessment and cost-benefit analyses. "The objectives of PPBS are to improve the chances that tax dollars will be allocated rationally and will have maximum effect in achieving stated purposes. These objectives require that effects can be measured."^[7]

Although much of the analytical research associated with the program approach, especially trend analysis, was sustained in military programs and in those related to welfare and housing well into the 1970s, program budgeting in practice died out fairly quickly. Controversy related to the war in Vietnam and Watergate, then subsequent stagflation and the energy crisis diverted the attention of the American public and government officials from a concentration on rational means for determining spending. The Reagan administration presented somewhat of a death knell on rational, comprehensive, and top-down assessment of what government should be doing, given its primary agenda of cutting both the size and presence of the federal government.

LASTING EFFECTS

It is difficult to calculate the success or failure of any given program budgeting system. No two systems are identical, and even application in one government is likely to be inconsistent across departments and divisions. Systems are rarely comprehensive. Realistically most budget reforms, program budgeting included, can lay little claim to effecting dramatic change in actual budgeted amounts or proportions. Yet, there is no doubt that program budgeting has left lasting impressions that flavor current budgeting initiatives. For example, strong components of modern performance-based budgeting reforms in the United States include requirements of budget justification, management improvement, and program success that are inherent to a program approach. What is different today with performance-based initiatives is an "enhanced emphasis in public organizations on quality, variety, customization, convenience, and timeliness of services and programs over and above economic efficiency concerns."^[8] Also, modern public organizations have equity concerns versus the cost assessments that overshadowed much of the analysis generated within the program budget format.

Today, the federal government maintains an emphasis on performance measurement and reporting begun in earnest during the first Clinton administration. The Government Performance and Results Act of 1993 requires performance measurement and tracking in federal agencies and established a schedule for performance reporting by these agencies. This system seemingly extends a strictly program approach by incorporating strategic planning, multiyear budgeting, and goal determination, along with more specific measurement development, information gathering and data analysis, and results assessment and reporting.

At the state level, most governments have some type of performance-based budgeting process formulated, if not completely instituted. Still, nine states characterize their budget approach as solely programmatic (Idaho, Illinois, Louisiana, Maine, Maryland, Massachusetts, Nevada, New Jersey, and Pennsylvania), while 13 states characterize their approach as both program and incremental. Nineteen states include program budgeting along with at least one or two other types of approaches, such as zero based or performance. Finally, nine states do not include program budgeting as an approach currently in use by their government (Alaska, Colorado, Georgia, Indiana, Missouri, New Hampshire, New Mexico, New York, and Washington).^[1]

Pennsylvania offers perhaps the most enduring example of program budgeting. This was originally an executive-driven initiative by Governor-elect Raymond P. Shafer in 1967 to support “good management.” At that time, eight program categories were created, seven that remain today (Table 1).

Factors supporting budget reform, in general, and program budgeting, specifically, are also enduring. Consideration of the many case assessments of program budgeting initiatives across governments in the United States yields several conclusions about the factors that can facilitate successful implementation. These include:

- The process must recognize and even encompass the political environment.
- There must be sustained leadership for the initiative, regardless of how prescribed.

Table 1 Program categories in the Pennsylvania state budget

Began with the following programs ^a	Today there remain these programs ^b
• Direction and supportive services • Protection of persons and property • Health-physical and mental well-being • Intellectual development and education • Social development • Economic development and income maintenance • Transportation and communication • Recreation and cultural enrichment	• Direction and supportive services • Protection of persons and property • Health and human services • Education • Economic development • Transportation and communication • Recreation and cultural enrichment

^aCommonwealth of Pennsylvania, Office of Administration, Bureau of the Budget, *The Budget Process in Pennsylvania*, December 1970.

^bCommonwealth of Pennsylvania, Office of the Budget, *The Budget Process in Pennsylvania*, May 1999. (These seven programs, as named, start with the 1988–1989 fiscal year.)

- There should be staggered introduction of the system to agencies.
- There must be ownership of the new/changed system via involvement up and down the hierarchy.
- There must be concerted application of resources:
 - There may be costs associated with the connection of the program structure with the budgeting and accounting system,
 - There will be costs associated with even minimal training of administration and staff regarding system requirements.
- There must be a realistic time frame for institutionalization of the system.
- Any reform is a continually evolving process that must allow for some flexibility to remain viable.

Perhaps the greatest “gift” related to the introduction of program budgeting is its requirement of systematic application of analysis to the study and interpretation of budgets. “Without accurate, comparable, and informative data, decision making will perforce continue to be based on guesswork and intuition.”^[7] Today, the plethora of performance-based budgeting initiatives, as well as advancement of accounting standards at all levels of government, can only enhance the capabilities of government officials for more rational budgeting. Of course, nothing will or should displace the political aspects related to public spending. Rather, the concern should be with providing an environment that supports the presentation and use of clearly formulated information and analysis related to government operations. “Reporting information on the results of government programs in government financial statements can improve the capacity to create such information in addition to developing a demand for it.”^[9]

Program Evaluation and Review Technique (PERT) and Critical Path Method (CPM)

Bradley J. Best

Department of Political Science, Buena Vista University, Storm Lake, Iowa, U.S.A.

Jeremy R.T. Lewis

Department of Political Science, Huntingdon College, Montgomery, Alabama, U.S.A.

INTRODUCTION

Program evaluation and review technique (PERT) and the critical path method (CPM) are used to plan, coordinate, and control the performance of activities that comprise complex projects. Designed as a tool for executing projects that are unique and non-repetitive, PERT methods typically include the preparation of a network diagram. Constructing a PERT diagram requires a manager to identify the interdependent phases of a project and the correct sequences of activities that lead to completion. Furthermore, when combined with applications of probability theory, PERT may be used to predict the duration of activities and forecast the complete date of a project.

Closely related to PERT, CPM techniques are used to guide project managers in making resource allocation decisions during the life of a project. Critical path method guides managers in identifying the sequence of activities that most directly influence the length of a project. Moreover, CPM enhances a manager's ability to use resources in an efficient way by providing a strategy for determining which activities can be expedited to minimize total project costs. Together, PERT and CPM rationalize the central tasks of project management—forecasting the completion date of projects, while coordinating resource allocations to maximize efficiency and effectiveness.

PERT: ORIGINS AND APPLICATIONS

Firmly rooted in the field of operations research, PERT/CPM shares a common theoretical lineage with the familiar techniques of linear programming and decisional analysis. Each method is dedicated to improving managerial decision making. Devised in the late 1950s by the firm of Booz-Allen Hamilton, PERT was first employed to schedule and control the performance of tasks necessary to construct the U.S. Navy's Polaris missile system. This project required the coordinated work of scores of contractors and

subcontractors. In addition, the large number of system components and the technological complexity of the project demanded a carefully orchestrated plan for construction. Moreover, PERT emerged as a method of sequencing and estimating the duration of activities in complex projects.

Program evaluation and review technique methods are not appropriate for all projects, but are best employed in projects that, for analytical and planning purposes, can be dissected into a series of distinct activities and events. Program evaluation and review technique is useful in planning for projects in which some or all activities must be performed in prescribed sequences. The task of identifying the proper sequencing and precedence relationships in a project requires that managers systematically reduce the project to a collection of distinct activities. When an activity can be performed only after the completion of another activity, there is said to be a precedential or dependent relationship between these tasks. Furthermore, PERT and CPM methods are jointly applicable to projects wherein a delay in the completion of one phase requires some adaptation, such as the dedication of additional resources to a key activity to realize a specified completion date for the entire project.

Program evaluation and review technique methods are gainfully used in projects that have identifiable points of initiation and conclusion. Thus, PERT is most useful in planning and controlling non-repetitive, non-cyclical projects. As Levin and Kirkpatrick observed, repetitive projects, such as the assembly-line manufacture of automobiles or the continuous provision of trash disposal services by a local or county government, are little improved by applications of PERT analysis.^[1] This is not to say that planning and controlling work processes is unnecessary in instances of repetitive projects. Rather, with each repetition data are generated to inform the planning and control functions that managers must perform in overseeing future iterations of production or service delivery. By contrast, managers of nonrepetitive projects must plan, coordinate, schedule, and control activities in the absence of experiences on which to

estimate the time necessary to complete those activities.^[1] Thus, planning for non-cyclical projects requires a system of scheduling and coordinating activities characterized by both multiple precedence relationships and complex streams of uncertainties. Program evaluation and review technique is a network planning technique developed to address these unique managerial challenges.

EVENTS AND ACTIVITIES IN PERT

When conducting PERT analysis, a project is defined as a collection of distinct, yet often interdependent activities that when performed in prescribed sequences attain some specific goal. Projects are typically represented using a network diagram—a visual depiction of the events and activities that link events. Preparation of a network diagram requires managers to both conceptualize an entire project and identify its many distinct activities. Construction of a network diagram calls upon project managers to identify the sequences of activities that will affect the efficient completion of a project.

An event is defined as the point of origin or completion of an activity. Events are depicted on the network diagram using letters either enclosed or adjacent to circles. If PERT methods were used to plan the construction of a large ship, one event on the network diagram may represent the beginning of work on the hull. A subsequent event would represent the completion of the hull and the commencement of the next phase of the project. Moreover, events consume no time and incur no personnel or material costs. Thus, events are included in the network diagram to reveal the boundaries of activities in project design.

Activities are defined as the processes that link events. Unlike events, activities consume time, require personnel, and incur other costs. An example of a simple project, such as the one depicted in Fig. 1, is useful in illustrating the distinction between events and activities in PERT analysis. Presume that our entire project consists of planting a small tree on the campus green and decorating it with small light bulbs. Event 1 is identified as the beginning of the project—the point at which we begin digging a hole suitable for a small tree. If the process of digging the hole is denoted as activity A, event 2 refers to the point at which the hole is complete.

Activities are the principal focus of PERT analysis. Consider the example presented in Fig. 1. Because we

must know when to have the light bulbs available at the site of the newly planted tree, it is essential that a manager produce a reliable estimate of the length of the digging and planting process, labeled activity B. Estimating the time necessary to complete activity B requires an elementary knowledge of probability theory.

APPLICATIONS OF PROBABILITY THEORY

A principal task of the project manager is to accurately forecast the completion date of a project. The accuracy with which project completion dates are identified is contingent on the planner's ability to assess the duration of critical tasks. Furthermore, the planning and scheduling functions of PERT are highly sensitive to the accuracy of estimated activity completion dates. The conventional method of identifying the expected length of an activity involves an application of probability theory.

Levin and Kirkpatrick explained that probability theory affords the planner a method of estimating activity completion dates in the absence of data on past iterations of the activity.^[1] Project planners know that, theoretically, a particular activity could be performed 1500 times and, on each occasion, the length of time needed to complete the activity could be recorded. As the authors pointed out, probability theory indicates that some completion times would occur more frequently than other completion times. In addition, some completion times would occur infrequently; in a few instances, the activity would be completed quickly and, in a small number of cases, the activity would consume an extraordinary length of time. Moreover, if an activity were performed a large number of times, a probability distribution of activity completion times would emerge. Considering Levin and Kirkpatrick's discussion, it follows that a project manager could use elementary statistics and the concept of a probability distribution to determine the likelihood of the activity being completed at any particular time.^[1]

Unique public projects are, by definition, performed on only a few occasions or only once. As a result, managers have no data with which to construct a probability distribution of activity completion times. However, the logic of probability theory can be applied to estimate the time needed to complete an activity. This estimate is commonly denoted as the expected completion time of an activity, and many scholars^[2-4]

Fig. 1 Events and activities in PERT diagram.

suggest that it may be calculated as follows:

$$t_{etc} = t_{opt} + 4t_{ml} + t_{pess}$$

In this mathematical expression, t_{etc} refers to the expected time for completion of the activity; t_{opt} refers to an optimistic forecast of the time needed to complete the activity; t_{ml} refers to the project planner's estimate of the most likely time necessary to complete the activity; and t_{pess} refers to a pessimistic forecast of the time needed to complete the activity. It is important that t_{etc} is a weighted average—the expected time for completion of an activity is, logically, most influenced by the value of t_{ml} .

Estimations of project completion dates can be made only when project planners are confident in their calculations of the expected completion times of activities. Wiest and Levy noted that, as the range of values between optimistic and pessimistic estimations increases, project planners should be less confident in their calculation of expected activity completion time.^[4] This reflects another implication of probability theory: as the statistical variance of estimated completion times increases for any particular activity, planners must adapt project schedules to the uncertainty that this introduces into estimations of activity completion dates. In these instances, project planners must prepare for activities to be completed in much less or notably more time than suggested by the value of t_{etc} .

THE CRITICAL PATH IN PERT ANALYSIS

The tasks of planning, scheduling, and controlling the performance of activities become more complicated when projects must be completed by a predetermined date. When a project must be completed by a particular date, managers must determine the most effective allocation of personnel and other resources among a large number of distinct tasks. The process of making these decisions is simplified by identifying the sequence of activities most likely to cause delays in the completion of the project. These activities are said to comprise the critical path on the network diagram.

In any project, the critical path is regarded as the most time-consuming sequence of activities and events. On simple PERT charts, the critical path may be identified by finding the route of activities from the project's origin to the project's completion that yields the largest sum of expected times for completion. It follows that the total amount of time needed to complete a project is equal to the total amount of time necessary to complete all critical activities. An important principle guiding PERT/CPM is that a delay in the completion of

any activity on the critical path, often referred to as a critical activity, will cause a delay in the completion of the project. This is to say that critical activities possess none of what is known as “slack.”

Understanding the concept of slack clarifies the distinction between critical activities and non-critical activities. Unlike critical activities, an activity that possesses slack may be delayed without triggering a delay in the completion of the entire project. For example, suppose that the latest time that activity X can be finished without jeopardizing the ultimate completion date of the project is the conclusion of week 10. If the earliest possible finish date of activity X is the conclusion of week 8, activity X possesses 2 weeks of total slack. Thus, assuming that the activity immediately preceding activity X is completed on or before its latest finish date, activity X could begin late or progress could be temporarily suspended provided that the activity is completed by the close of week 10. As a project is underway, planners typically recalculate the slack time associated with events on the PERT chart, and refer to these figures when making scheduling and resource allocation decisions.

How do managers identify the critical path and assess the amount of slack associated with non-critical tasks? Computer software packages are available to project managers for the purpose of quickly ascertaining the critical path and slack times associated with complex projects. However, it is also possible to generate the same information using simple mathematics. The ability to do so reflects a more thorough understanding of key concepts used in PERT/CPM. A simple project with multiple sequences of dependent tasks is useful in demonstrating the process of finding the critical path and ascertaining the amount of slack in noncritical activities.

The process of finding the critical path involves calculation of the total slack associated with activities on the PERT diagram. Critical activities are those activities with zero slack. Furthermore, the critical path consists of the sequence of dependent activities that have zero slack. Identifying those activities with zero slack requires calculation of the latest start time and the earliest start time or, alternatively, the latest finish time and earliest finish time, for each activity on the network diagram.

The first step in calculating total slack is to employ the forward pass procedure.^a This involves the calculation of the earliest finish time for each activity, beginning with the event that signals the initiation of the project. In the project depicted in Fig. 2, the leftmost

^aA detailed explanation of the forward and backward pass procedures can be found in Ref.^[4]. For an alternative explanation of the forward and backward pass procedures, see Ref.^[5].

Fig. 2 PERT diagram with expected duration of activities.

node represents the start of the project and the commencement of the first activities. For each activity, the earliest finish time is equal to the earliest time that the activity could begin in addition to the time needed to complete the activity. For example, the earliest start time for activity E is, obviously, zero; at the initiation of activity E, no time has elapsed on the project schedule. Considering that the duration of activity E is 2, its earliest finish time is also 2. Due to the precedence relationship between activities E and F, activity F may begin only when E is complete. Therefore, the earliest finish time for activity F is 5, or the sum of its earliest start time and its duration, which are 2 and 3, respectively. A complete listing of early finish times for all activities is presented in Table 1.

The latest start time for each activity is determined using what is commonly referred to as the backward pass. Beginning with the event that signals the completion of the project (i.e., the terminal node), the latest finish time for each activity is determined. The latest start time for each activity is calculated by subtracting the duration of the activity from the latest finish time. For example, as indicated by Fig. 2, the project must end with the fifteenth time period, the moment that activity D is finished. Considering this, the latest finish time for activity D is 15 and its duration is 1. Thus, the latest start time for activity D is 14. Activity C, the task immediately prior to activity D, requires three time periods for completion. In view of the fact that the latest start time for activity D is 14, activity C must be completed no later than 14. Subtracting 14, the

latest finish time for activity C, from the length of time needed to complete C, which is 3, produces a latest start time of 11 for this activity. Table 1 relates the latest finish and latest start times for each activity in the PERT diagram.

Also depicted in Table 1 is the slack associated with each activity presented in the PERT diagram. Activities A and B possess slack. Activity B, for example, could be finished as early as time period 8 or as late as time period 11. Provided that activity B is completed by time period 11, a delay in the initiation of this activity will not adversely affect the completion date of the project. By contrast, activities C, D, E, F, and G possess no slack. For each, the difference between their earliest and latest finish times is zero. A delay in the start or completion of one or more of these activities will compromise the completion date of the entire project. Therefore, activities C, D, E, F, and G comprise the critical path.

Recall that when constructing a PERT chart, an expected time of completion—a weighted average of optimistic, most likely, and pessimistic projections of activity completion times—is generated and used to schedule sequential activities. The search for the critical path differs in that for each activity project planners employ only one time estimate. As a result, estimations of the critical path are dubious where there is much uncertainty about the duration of critical activities. In fact, mistakes in estimating the duration of activities may cause managers to incorrectly assign tasks to the list of critical activities.

It is assumed that projects must be completed with limited resources and that delays in project completion dates are to be avoided. Thus, managers often want to redirect resources to critical activities to shorten the critical path or remedy an anticipated delay in the completion of a critical activity. Knowing the location and quantity of slack in a project facilitates a manager's need, in some instances, to direct resources away from slack activities toward critical activities in the hope of either avoiding a delay in project completion or shortening the critical path. Although it may increase total project costs, managers can also seek additional resources that can be applied to critical activities in the interests of shortening the critical path and overall project completion time.

When deciding to shorten the length of the critical path by directing additional resources at one or more

Table 1 Start and finish times for activities on the PERT diagram

Activity	LS	ES	LF	EF	Slack	Critical activity?
A	3	0	9	6	3	No

G	5	5	11	11	0	Yes

Note: LS, latest start; ES, earliest start; LF, latest finish; EF, earliest finish; Slack, LF-EF.

critical activities, a process known as “crashing,” a manager must determine how to achieve this result at the lowest cost. Thus, project managers are guided by concerns for efficiency when determining which activities to expedite. Critical path method dictates that shortening the critical path, and, relatedly, the length of the project, is rational only to the extent that doing so either reduces total project costs or increases project costs to an acceptable limit. For example, if a delay in the project completion date is deemed less costly than a crashing strategy, no effort at expediting an activity should be undertaken. It may be that crashing one activity yields a shortened project duration and lower total project costs, but the cost of crashing a second or third activity produces no reduction in project length that yields a cost savings. Determining whether to initiate a crashing scheme, which activities to expedite, and the order in which activities should be expedited are the principal goals of CPM.

In its most basic form, CPM involves a search for the critical activity that can be shortened at the lowest cost. In fact, the costs and benefits of crashing all other critical activities should be ranked, beginning with the activity that can be crashed with the most efficient result. Critical path method dictates that this process continues as long as other critical activities can be crashed to produce savings in project costs.^b

CONCLUSION

Originating in the late 1950s, PERT and CPM remain two of the most important techniques for rationalizing decision-making processes in the public and private sectors. As a result, instruction in each method is a standard feature of courses in project management. Yet, PERT and CPM are little addressed in current scholarship; both techniques are part of the conventional stock of knowledge in management science. Neither method is a source of new theoretical development in the public administration field.

Public Administration as Management

Lawrence F. Keller

*Public Administration Program, Cleveland State University,
Cleveland, Ohio, U.S.A.*

INTRODUCTION

Public administration began, and the mainstream continues, as a system of management for complex public organizations. From its founding around the turn of the twentieth century during the Progressive era, the field if not profession has focused on the rational running of the public sector. Philosophically, the rational approach is derived from the Enlightenment, a philosophical movement aimed at replacing tradition and similar non-reasoned-based foundations for social action.^[1] The approach underlies most of modern life and, although heavily criticized in some quarters,^[2] shows little sign of abating.

LIMITS TO A MANAGEMENT PERSPECTIVE

The result is a powerful and highly efficient system for operating public organizations. The evolution of this system is the focus of this article. However, it may first be useful to note what has not been part of, or has been difficult to reconcile with, management qua public administration. This highlights both the nature of management in public administration and the limits of the field from a managerial perspective.

Political philosophy has been difficult to reconcile with what Max Weber termed legal-rational organizations.^[3] As a result, public administration as management fostered organizations that were internally authoritarian and externally divorced from politics.^[4,5] They reflected more a belief in the power of a rational management than implementation of a political philosophy.

In addition, public administration as management tended to reduce law to strict rules for conducting daily business and establishing managerial ethics. The result was an emphasis on the contribution of law to rationality rather than as part of the political structure of a democratic republic. Leonard White underscored this in the first public administration textbook in 1927, arguing that public administration should be based on management principles and not law.^[6]

Finally, management was considered a rational activity in the context of an organization. This made it difficult for public administration to handle relations

among organizations and within networks. The focus continues to be on the development and implementation of rational methods for efficiently managing organizations vested with public purposes. History illuminates how this focus came to dominate the field.

DEVELOPMENT OF PUBLIC ADMINISTRATION AS MANAGEMENT

After the Civil War, the United States underwent dramatic changes. The development was quite uneven, with the Northeast and Midwest entering the Industrial Age. This section underwent dramatic urban development, with New York City, for example, adding 1 million people every decade between 1880 and 1920. In the same years, Cleveland rose from a city of 50,000 to a metropolis of 720,000. Many citizens of these cities and often a majority of the laborers in the factories were immigrants.

Simultaneously, the South turned into a racially divided Third World environment, and the West was the scene of battles between the Native Americans and the Army. Much of the urban and industrial development occurred in and after the 1880s, when Reconstruction of the South was abandoned. The abandonment freed the Republican party to pursue industrial policies but imperiled race relations.^[7] Such relations would not be addressed seriously for almost 100 years, until the tumultuous 1960s.

A primary need during this rapid development was a method or methods for running large-scale production. With the advent of the railroad, production could be scheduled yearround. Simultaneously, large amounts of supplies could be shipped to, and a large amount of output shipped out of, a plant. Initial organization of plants was around a foremen system (and it was only a male world until World War II), with foremen responsible for recruiting and directing teams of employees. The foremen system connected work with ethnic neighborhoods as foremen recruited from their neighborhood. However, it complicated coordination of activities and was soon replaced with scientific management, a system in which a staff of planners determined the work process.^[8,9] Scientific management rationalized the work process, stressing

maximum efficiency. Interestingly, breaks and other activities were instituted as they promoted production. The system was a highly rational one, with little or no account of the social or psychological side of human activity. (This outcome was delightfully captured in the movie, “Cheaper by the Dozen,” and detailed in the Hawthorne Plant research.)

Public administration during the Progressive era was largely an urban practice. Initially, concepts of management reflected perspectives on community.^[10] For many, it was an attempt to shape American cities along the lines of the ancient polis, such as Athens or Rome. For others, it was a process for improving the morals of urban life. Thus, many cities established juvenile facilities, usually in the country side, where the separation from adult criminals and the beneficial environment of rural life could save otherwise lost young souls. Finally, for many reformers it was a battle against political machines and what they called “privilege.” Many advocated public ownership of utilities, such as electricity and water, as a way to avoid political privileges granted to a few, that is, those who owned such facilities. However, by the end of the era, the start of the 1920s, reform began focusing on managing the urban organization. Attempts at improving the community were jettisoned from the field of public administration because the concern was with managing the increasingly complex public organization.

Thus, the initial thrust of management in both the public and private sectors was on rationalizing production. Although often not successful in implementing the full version of scientific management, illustrated by Taylor’s testimony to a curious Congress, the rationalization of production became a permanent part of both public and private management. From this perspective, design of work processes was a conscious maximization of efficiency.

By the 1920s, production had ceased to be the primary concern. The management of large-scale organizations became the main issue. In fact, economic development was promoted by the rapid consolidation of industries, leading to monopolies with names such as the United States Steel, National Biscuit Company, and Standard Oil.^[11] Antitrust was partially successful in reducing some monopolies, but the resulting companies were still quite large, often involving multiple plants and needing more effective management.

In the 1930s, the national government developed rapidly. The development was a crisis-driven process that seemed to be chaotic to most reformers. As political opponents often called attention to the chaotic process, President Franklin D. Roosevelt enlisted reformers from public administration to address the

issue. The Brownlow Commission^[12] established the foundation for American public administration with its study of and answers to the organization of the executive branch of the federal government. As part of the Brownlow Commission effort, public administration scholars of the time were recruited by Luther Gulick and Lyndall Urwick to write on the various dimensions of public administration as management. The resulting *Notes on the Theory of Organization*^[13] created the most famous of many management acronyms, POSDCORB (Planning, Organizing, Staffing, Directing, Coordinating, Reporting, and Budgeting). In essence, public administration as management was based on perceived universal principles that constituted effective management of any organization in any culture.

In public administration, management became the sole concern of the executive branch, which developed several key staff agencies with broad mandates and direct access to the Office of President. For example, the Bureau of the Budget, a reform created more than a decade earlier, was moved from the Treasury Department to the newly created Executive Office of the President. Later, the name was changed to the Office of Management and Budget in recognition of the larger roles such staff agencies play.

This general view of public administration was clearly depicted in an earlier novel, *Philip Dru, Administrator*, circulated in unpublished form.^[14] Later, the work was attributed to Woodrow Wilson’s Chief of Staff, Colonel House. In the book, Mr. Dru is appointed Administrator of the United States after a second civil war. After successfully solving American public problems by the end of his 6-year term, he sails to the Soviet Union to become their administrator. The universality reflected, as did the earlier scientific management view of production, the application of science to public administration. For these intrepid practitioners and creators of science, no problem could escape solution if the proper technique were applied. Science would disclose, in unambiguous results, the proper technique. Thus, a robust science of public administration would establish a rational system of solving social problems through the agency of rational management.

At this time, the late 1930s, the American Society for Public Administration (ASPA) was founded. The ASPA deliberately used the preposition “for” in their name to call attention to the organization as a catalyst for action.^[15] The ASPA published the *Public Administration Review*, which became, and has remained, the leading journal in the field. Most of the published articles examine some aspect of management, reflecting the dominant view of the field as public management.

It is indeed a review of public administration as management.

Neoclassical Management

After World War II, a new group of academics began investigating the field. Many challenged the managerial focus—some because of the manner in which management was studied and delineated, others because of the exclusion of politics and philosophy. Dwight Waldo is the most notable example of the latter researchers. His *Administrative State*^[16] illuminated the political roots and consequences of public administration as management, often implicit in much of the literature, and created the phrase that for most captures the resulting polity. This vast literature is beyond this article, which focuses on the former researchers, those who attempted to improve public administration as management.

The most noted of these researchers, and a Nobel Prize winner for his efforts, was Herbert Simon. Simon did a frontal assault on traditional public management, arguing that the so-called principles were nothing but “homilies.” He based his research on logical positivism, the first explicit scientific development of management in the field.^[17] He focused on decision making, distinguishing, in line with his positivistic approach, facts from values. Management for him created organizational systems that efficiently provide factual and value premises to the proper decision maker at the appropriate time. In the first edition of his classic, he distinguished a science of administration from what he called “sociology” of administration. In later editions, he avoided such a stark distinction, but clearly perceived the management of an organization to be a more rational process than other organizational activities.

In line with his scientific approach, he created a more realistic portrait of the administrator. Although earlier writers talked about science, they were actually engaged in what Merton calls technology.^[18] They did not engage in science, but rather used experience and formal logic in a less than rigorous fashion. Thus, Simon’s critique was devastating to the scientific validity of much of the previous management literature. In the classic work titled simply, *Organizations*, March and Simon summarized the empirical findings on management.^[19] The book is an extensive, nearly endless compilation of findings. It illustrates well the results of a careful, truly scientific approach to management.

Although Simon criticized the earlier management literature, he was in turn criticized by Argyris and others concerned with the human variable of organizational life.^[20] Simon and Argyris participated in a

classic dialog in *Public Administration Review*,^[21,22] in which Argyris maintained that efficient organizations were inhospitable to healthy individuals. The scientific base of management selected by Simon did not address the psychological needs of workers in a unified manner. In line with the rational approach of public administration as management, Simon, especially in Simon and March, noted the psychological needs more from a management perspective than from a concern with the health of organizational members. In essence, Simon strengthened the scientific base of management, but did not enlarge its scope or fundamentally shift it from a rationalistic approach.

CONTEMPORARY PUBLIC MANAGEMENT

A final strand of public administration as management emerged in the 1970s and 1980s. During this era, perceptions of government changed. In contrast to the images of public agencies as effective agents of beneficial social change, an image existing since the 1930s, many challenged the ability, or even the legitimacy, of government. The challenge was in part a response to calls for a more active public service, one centered on social equity. Starting with a conference of young administrators and academics held at Minnowbrook, a retreat for Syracuse University, the movement called for administrators to be more politically oriented in terms of the effects of public policies on vulnerable groups.^[23] Although the effort engaged many scholars in extensive debates, it had little effect on the nature of public management. However, it did reflect the general belief in public administration as an agency for social change.

The challengers to an active public service addressing social equity often painted government agencies as ineffective and out of touch with the needs and desires of the citizens. More extreme critiques perceived public agencies as oppressive and pursuing elitist, non-democratic agendas. Some wanted very limited government, recalling the political philosophy of Thomas Jefferson. Others wanted to reform public administration, emphasizing responsiveness to the service demands of citizens. A former city manager and an organizational consultant, Ted Gaebler and David Osborne, personified the latter group of management reformers. They called for the reinvention of government by creating an organizational culture centered on managerial empowerment and entrepreneurial policy making.^[24]

Their call and perspective became the centerpiece of President Clinton’s reform of the federal government. Vice President Gore headed a task force that produced a blueprint for a more responsive federal government, one whose civil servants were empowered to meet

service demands without the stultifying restraints of bureaucracy.^[25] President Clinton stated the goals of the National Performance Review, later the National Partnership for Reinventing Government, in the following terms:

Our goal is to make the entire federal government less expensive and more efficient, and to change the culture of our national bureaucracy away from complacency and entitlement toward initiative and empowerment.

The effort continued throughout the Clinton administration and was the most visible reinventing project. Although the results were debated, both in terms of what was produced and what should have been produced, they were part of a new perspective on public management. This perspective embraced notions of a market and customers, and called on public organizations to create and sustain organizational cultures responsive to the needs of their customers. In the field, the movement became known as the “new public management.” The emphasis was on empowering front-line managers—those who interacted with customers—reducing the bureaucratic overhead of public organizations and decentralizing government generally. An OECD report in 1997 stated, “a new paradigm for public management has emerged, aiming at fostering a performance-oriented culture in a less centralised public sector.”

A researcher identified nine characteristics of the new public management:^[26]

1. Devolving authority, providing flexibility
2. Ensuring performance, control, [and] accountability
3. Developing competition and choice, market-type mechanisms
4. Providing responsive services, client orientation
5. Improving the management of human resources
6. Optimizing information technology
7. Improving the quality of regulation
8. Strengthening the steering functions at the center
9. Private sector-style management

This new thrust, in contrast to previous foci on internal production and organizational control, centered on the interface between the organization and those who were putatively served. The criteria for agency performance were generally taken from economics, emphasizing meeting the needs of those who were to be served. Front-line managers, those who either meet or manage those who meet the clientele, were to be empowered, particularly in the creation of procedural policies. Human resource management

was a concern as the effort required the ability to recruit and reward responsive managers. The human resource thrust continued the policies of civil service reform, conceptualizing management along the lines of and rewarding performance in accordance with private, for-profit management.

In addition, many called for measurement of agency performance, documenting the extent to which agencies fulfilled their mandates and satisfied their customers. These techniques were aided by the extensive development of financial management, culminating in the generally accepted accounting principles (GAAP).^a In contrast to the management in general in public administration, financial management has developed some robust technologies that have been generally implemented. This paved the way for implementation of GAAP, providing effective financial assessment of government.

Human resource management has also created some powerful technologies. Perhaps not as uniformly developed or accepted as is the case with financial management, public administration as management has incorporated many lessons from other fields such as psychology into managing human capital. However, such advances have not been fully integrated into general notions of management in public administration, which despite considerable criticism and research to the contrary still relies on decades old principles.

Although the new public management was part of the reform of government, aimed at reducing the bureaucratic restraints and more conveniently meeting the needs of agency customers, it continued the efficiency criterion of classical management theory. The streamlining of procedures and the rewarding of responsiveness also followed rational models of organization. As a result, the core of public administration as management was continued although the politics of the field were greatly changed.

CONTEMPORARY PUBLIC ADMINISTRATION AS MANAGEMENT

Public administration as management has developed some powerful technologies that greatly contribute to modern governance. This is particularly true with regard to financial management, where professional management has been extensively practiced and

^aFor information on the Generally Accepted Accounting Principles, see the *Yellow Book*, actually titled *Government Auditing Standards*, published by the General Accounting Office, which contains information on both traditional accounting as well as performance auditing.

generally accepted. Even in governments that are generally less than professional, the financial arm meets many professional standards. In large part, this is a consequence of extensive funding of state and local government by the federal government with a consequent demand for accurate accounting of the funds. The application of professional accounting and auditing standards has also contributed. It has been facilitated by creation of techniques such as program budgets and performance audits. Agencies such as the General Accounting Office (GAO) at the federal level have successfully used such techniques.

Similar advances were made in performance measurement. These were to become a significant part of the new public management. One of the earliest efforts was by Herbert Simon, then working with the International Association of City/County Managers.^[27] Some sophisticated technologies permit monitoring achievement of objectives. The rapid advance of the computer and associated information technologies greatly aided such efforts. Conceptually, Simon's frame of management as decision making provided a method for designing information systems. In fact, Simon turned to researching such systems, as well as artificial intelligence, abandoning the field of general management.

To a lesser extent, advances were made in HR management. Incorporating findings and frames from psychology, sociology, and business administration, as well as indigenously in public administration research, robust technologies were created for improving human relations within organizations. For example, the Myers-Briggs assessment of personal activity preference is often used to illustrate the different ways in which people work. This not only promotes tolerance, but also increases understanding about, and the ability of, diverse people to improve work efficiency greatly.

In contrast to the advances in these subfields, public administration as management relies in great part on the early principles. Despite the penetrating criticisms from Simon to Terry, public management has not changed greatly in nearly 100 years.^[28] One suspects the staying power reflects its general utility, both for running complex organizations and for coping with the increasingly political environment of public administration. Similarly, there is no concept more criticized yet more often invoked than the politics administration dichotomy. For the near future, it appears that public administration as management will continue to hone the technologies of its subfields, while implementing classical management in relatively traditional patterns.

In the long term, public administration as management will continue to seek integration into public administration as governance. Such integration

will most probably be difficult, if not impossible. Conceptually, such a quest may parallel the hope for a unified theory in physics. In physics, micro- and macrolevels have resisted explanation via a general theory. Politically, the difficulty of integrating rational management and political governance may reflect a Madisonian political culture and system. In such a system, unification of management and politics may be perceived as creating potentially dangerous authority; in fact, such a unified authority could endanger the system itself. Perhaps much of the criticism of public administration as management is a political critique of its tendency to use powerful technologies through a centralized chief executive divorced from a meaningful political philosophy.

Historically, such a concern is definitely justifiable. The suppression of individual rights and national mobilization during World War I, culminating in the Red Scare in 1920, illustrates dramatically how centralized authority driven by fierce implementation of managerial technologies can endanger the system itself. Eric Foner writes that to the Progressives, "the war offered the possibility of rationalizing American society, instilling a sense of national unity and self-sacrifice, and imposing justice in labor relations. That American power could disseminate Progressive values around the globe heightened the war's appeal." Foner quotes John Dewey, who wrote in the *New Republic*, a journal started by the Progressives and illustrating well what they thought of the political context, urging "Progressives to recognize the 'social possibilities of war.' The crisis, offered the prospect of 'the more conscious and extensive use of science for communal purposes'." With few exceptions, the American Progressives agreed with Dewey's assessment and were willing to sacrifice some rights for a "more effective freedom."^[29]

In his famous work on the Progressive era, Robert Wiebe wrote of *The Search for Order* in what the Progressives called the "New Republic." In a chapter entitled, "The Illusion of Fulfillment," he wrote about the migration of Progressive focus from its initial concern with the modern city to the nation:^[30]

Success had bred confidence among urban and state reformers, and rather than undertake more of the same, they moved outward. Progressivism contained an inherent expansive thrust, partly from its need for ever-broader legislation, partly from its all-conquering optimism, but even more from its faith in method. If the right technique guaranteed the right results, no problems, whatever the size and scope, could withstand its magic.... They would join these millions of Americans [in all manner of movements] in a single crusade against inefficiency and injustice of special privilege, social ignorance, and habitual indifference.

... Such men as Frederic Howe and Walter Rauschenbusch not only encouraged local progressives to think of themselves as part of one grand drive, but they also supplied the rationale for integration: the skeleton of stages to an inevitable triumph, fleshed out with a new national intelligence; and at its heart the wonders of rational management.

In light of the possible mischief in the application of rationalism, and even more so its embodiment in powerful technologies at the disposal of highly partisan and political chief executives enacting political ambition, the field may well content itself with a muddling-through approach.^[31] This would implement powerful technologies in selected areas, while recognizing and respecting core political values and individual rights. Public administration as management must begin to put political philosophy on par with rational methods even though this may be somewhat inefficient. In essence, public administration as management must recognize it is part of politics and not a crusade of science driven by experts with visions of a one and true society.^[32] The creation of powerful financial tools demonstrates that public administration as management can play meaningful political roles through professional standards. The danger is in extending rational tools into a rational system. Both history and philosophy caution against such an extension, and can serve as excellent guides to a future of professional and effective public management in a constitutional political system in which public administration also performs critical governance responsibilities.

INTRODUCTION

This article argues that public administration uses philosophy as a lens of understanding and that the current lenses available to us are inadequate for the twenty-first century. Possibly the metaphor of eyeglasses that we use to enhance our eyesight is the best means to explain the argument in this article. When we are young, we may be lucky enough not to need eyeglasses, but many of us soon have to get them to bring our eyesight up to a standard that permits us to function in our environment. As we grow older, our prescription often needs to change, as we change. This article argues that humankind has also grown older. As that aging process occurred due largely to technological change, humankind needed to and did change its prescription to adapt to its changed circumstances. The twenty-first century is an extension of that evolutionary process of humankind and the various prescriptions, called philosophy, are again inadequate, especially in the area of ethics and morality in public administration. We need an enhanced or improved prescription to help us in the twenty-first century with its technologically dependent society.

Joseph Rost argued that the world is experiencing a radical transformation, which futurists claim change the basic values of the present era.^[1] Charles Garofalo predicted that the rational, male, technocrat, quantitative, goal-dominated, cost-benefit driven, hierarchical, short-term, pragmatic, materialistic model must give way to a new kind of leadership based on different assumptions and values.^[2] Garofalo also asserted that a pervasive sense exists that our fundamental perspectives on life are radically different from previous times, and any new values or perspectives built on the past paradigms are no longer adequate for the next century. According to him, “our civilization is

unbalanced, with our material culture far ahead of our ethical and moral independence.”^[2]

This article makes the case for a fundamental change in perspective, or a “lens change” in the vocabulary of our metaphor, in public administration. This article also explains the basics of that desired change. The first section after this introduction explains why we need to rethink philosophy, especially its role in the public sector. The next section critiques modernist and postmodernist philosophy, and makes the case for not using the fundamental assumptions that underlie those philosophies. Last, this article proposes a more useful, twenty-first century approach to rethinking the philosophical lens for public administration.

RETHINKING PHILOSOPHY

The Role of Philosophy

In thinking about the role of philosophy in the public sector, some consider philosophy as a means to explain phenomena and answer larger questions, such as the nature of understanding, the basis to judge good and evil, or the proper role of government in society. This article views philosophy as a conceptual lens through which we understand the thoughts and phenomena about those important fundamental matters. From those understandings, we then proceed to act and manifest behavior that our philosophy thus largely creates.

Although a strong influence on humankind, philosophy is also a dependent variable that society shapes. However, before that, key technologies shape society. Philosophy is a product of linear influence or, more properly in many cases, a synergistic influence with society. Alvin Tofler’s *Future Shock* dramatically presented the importance and influence of technology on

society.^[3] In that book, the driving force changing society was not philosophy, but rather technology. For example, the invention and eventual use of gunpowder revolutionized the art of war by ending the importance of the defensive castle that was key to the decentralized power relationships of the baron to the king in feudalism. Gunpowder strengthened the role of the crown and greatly strengthened the power of what eventually became the nation state. Another example was the invention of the precise clock, which meant that accurate navigation by longitude became possible. In turn, this meant that an economic philosophy built on mercantilism was not only possible, but also a superior means than war to increase the wealth of the emerging nation states such as England.

A major thesis of this article is that certain key technologies in various eras drive and shape society so that eventually the old lens becomes increasingly less functional, and that we need a new lens to better conduct ourselves in that revised society. New technologies will always advantage the people in society who are most able to adapt and think in new ways. They quickly comprehend their advantages and adapt their lens of understanding accordingly. As a result, in the evolved society, they tend to be more successful than others in terms of wealth, power, or both. Others may be slower to recognize the changing opportunities, but eventually they learn by experience and the demonstrated successes of those that adapted earlier. As their success becomes more obvious, others follow the example of success. In the past 200-year period, the two defining technologies are industrialization and information. In their respective eras, each had broad and remarkable impacts on almost every aspect of society.

As society changes, intellectuals cast about for new lenses to use to understand the conditions that are changing their lives. New philosophies are born as the older lenses become inadequate to explain the shifting paradigm brought on by technological change. For example, industrialization resulted in concentration of wealth and political power in the hands of a few economic barons. In turn, this situation meant that government could take over or control those limited power centers with an administrative state. The lenses to accomplish that end were socialism and progressivism that both accepted and championed the primary role of the state in society.

Philosophy acts as a mental filter for the more intellectual among humankind, and it is also the bases for humankind to act and make judgments in ways defined by the particular philosophy. Because philosophy has influence, it advantages and disadvantages various groups in society. Over time, if the philosophy is a good lens on society, the advantaged groups prosper and gain increasing power. Commonly, even the disadvantaged groups begin to adopt the philosophy

of the successful groups if the new ruling elite permits them. A good example is the invention of modernism. In Western Europe, modernism fit the new industrial society particularly well because the so-called objective empirical inquiry using the so-called scientific method tended to create functional knowledge for the advantaged elite groups. Those industrial and government groups tended to prosper and other societies around the world saw the remarkable successes, and began to emulate them and adopt modernism.

Modernism and Public Administration Theory

Contemporary public administration can be thought of in terms of modernist thinking and, to a much lesser degree, various counter perspectives. Less directly, but nevertheless significant, are the premoderns: Plato and Jesus. Few would argue that Plato did not influence Western thought, but with the American and eventually the Western tradition of secularization, intellectuals rarely speak of their faith traditions except within the walls of houses of worship.

Nevertheless, faith and especially Christianity radically influenced Western thought and particularly the views of the premodernists. For example, the faith traditions of Judaism and Christianity with its stress on the 10 commandments and the golden rule still define today what people accept as fundamental rights and wrongs in society. In the premodern society, interpretations of religious texts heavily influenced the very conduct of what intellectuals considered proper inquiry that advanced human knowledge. For example, interpretations of religious texts in the Middle Ages brought intellectuals to think that the center of the universe was the earth and thus leaders punished scholars that dared to be politically incorrect thinkers. In defining the modernist, Rene Descartes and Francis Bacon are important, but so are Jeremy Bentham, John Locke, and Adam Smith, who also significantly refined the modernist "lens." These philosophers were secular thinkers that focused on the good of the people as defined by rigorous rational thought associated with the scientific method. Many of them defined nineteenth-century liberalism with its distrust of government as a social instrument. They had great faith in the rational thinking capacity of mankind to discover, articulate, and apply knowledge. In contemporary language, the term "liberal" shifted in meaning, primarily due to progressives in America and socialists in Europe, who embraced and envisioned government as a social instrument unlike the earlier nineteenth-century liberals. In both the nineteenth and the twentieth centuries, the hallmark of modernists is their faith in human reason to discover truth and use it to improve the human condition. Modern science is a product of that faith.^[4,5]

One could easily stop with the modernists as their influence is so significant on Western thought, but there are other views that were becoming increasingly heard and influential. Two philosophers, David Hume and Edmund Burke, questioned the capability of human reason to seek out and find knowledge that could guide our civilization with sufficient certainty. Later modernist opponents were Jean-Paul Sartre, John Rawls, and the school of thought known as phenomenology. Each builds on earlier philosophers and challenges the fundamental core of modernist thought.^[6-8]

Modernism, such as developed and used by John Locke and Jeremy Bentham, biases human thinking toward left-brain analytical thinking and away from religious right brain thinking that dominated the very being of human behavior in the previous centuries prior to the arrival of modernism. With modernism, religious thinking became marginalized and even dysfunctional. Modernism advantaged gifted analytical left-brain thinkers, who enjoyed great success in society. However, right brain thinking did not disappear, but those who thought in that manner were less central to power and economic success. Especially among the world's intellectuals, power became secularized and religious thought became decreasingly important even in such matters as values and ethics.

Postmodernism and Public Administration Theory

Possibly because of later modernist opposition due to partly the popular discontent with government policy in the developed world, there was an increasing direct challenge to modernist thinking. Postmodernism arose first with Friedrich Nietzsche, but gained much of its current direction from Ludwig Wittgenstein, who had abandoned his earlier version of modernism called logical positivism. Most cite Friedrich Nietzsche as the first postmodern philosopher, and many would agree that Ludwig Wittgenstein was the most influential in the more contemporary group of such thinkers. If one had to cite an area that developed the philosophy the most, clearly France is where this philosophy found its most fertile ground to grow.^[9]

Various concepts and vocabulary populate the postmodern universe. For example, postmodern thought is the rejection of universalism, essentialism, ontological realism, and metanarratives. In other words, postmodern thought rejects any absolute ahistorical and universal truths such as God or a universal knowledge based on science. They even reject the quest for such truths.

The lens of postmodernism sees multiple paradigms in which one paradigm believer cannot logically

dispute the correctness of another paradigm believer. However, within a paradigm or localized logic, we can use language games to at least rule out some non-sensical reasoning. For postmodernists, the self is not subjectively determined, but largely influenced by the inherited language games of the time and culture. There is no centered unified self, but rather we are split between our conscious and unconscious. Knowledge is merely institutional rules that guide our discourse and our actions. Truth is merely vocabulary that arbitrarily defines itself as truth.

To postmodernists, no definition is possible for fundamental concepts such as "being." Words are only weak, but necessary, abstractions of abstractions and nothing more. Thus, language, the vehicle of communication, limits full and complete interconnective understandings among humankind because each person must speak from their *relative* position in the universe. According to its adherents, postmodern thought does contribute to public administration theory. For example, it teaches us the foolishness of most so-called policy decisions that are meant to be universal or broad in implication. We also learn from postmodernism that organization structure is in itself a system of power. Last, we learn that reality is not important, but rather what is important is the measure that we use to indicate the condition of reality.^[10,11]

Philosophy does influence the way humans see, understand, and judge. Philosophy does not advantage all humans in exactly the same way because other factors such as heritage and social conditions are also important. Nevertheless, philosophy is a remarkably powerful influence on humankind in general and on some people in particular.

CRITIQUE OF MODERNIST AND POSTMODERNIST PHILOSOPHY

Certainly, humankind is at its historical zenith and modernist philosophy, in particular, can take some of the credit. Today, modernism leads humankind to believe that it can eventually know everything and with knowledge there are no limits. Postmodernism is an active minority voice of realism that questions the optimism of the modernist and takes some of the authority out of what could be an intellectual tyranny. Because of modernism, humankind concentrated on developing left-brain analytical capabilities. In contrast, postmodernism reminds humankind that the left brain is insufficient. Thus, the two contesting yin and yang positions present humankind with a balance that not only is inconsistent, but also dynamic and functional. Nevertheless, this article argues that both are inadequate for the twenty-first century.

Modernism and postmodernism thinking place belief in an ultimate truth or absolute as either beside the point or simply not relevant. We do not need to debate the role of doubt in philosophy again as did Descartes, but this article needs to discuss the issue of the absolute's existence, as it is central to our theme. Postmodernism adopts a relativist perspective that only accepts judgments of truth within the confines of a single paradigm. Modernists adopt a temporary version of truth that is subject to continual revision. In a pragmatic sense, neither accepts a fundamental or universal permanent truth, especially the existence of an absolute. By different paths, both produce the same result—both say essentially that truth is relative, as are ultimate values including ethics.

What are the consequences of relative values and ethics? Relative values and relative ethics are a certain formula for human conflict in which a few can terrorize the many because they are so certain of their beliefs and so dismissive of the beliefs of others. With modernism and postmodernism, consensus or capitulation is the only means to resolve conflict between parties. With modernism and postmodernism, there is no ultimate means to settle a dispute by appealing logically to ethics or morality.

With those two lenses of understanding, we only consider people who oppose us as not being consistent with our understanding; they can never be correct because no such condition exists. Our lenses focus our understanding on the temporary nature of truth or the impossibility of thinking that truth exists between people who hold different paradigms of understanding. Such a reasoning process not only leads to openness, but also creates a cynicism among the premodernists that we commonly call fundamentalists in religious traditions. Such premodernists do not see the value of consensus and what the other groups claim to know. That cynicism can provide the premodernist the rationale to continually bring terror to the many.

Is there an escape from this philosophic cul de sac? Yes, but we must first understand that we can conceptualize the altruistic/materialistic, rational, and government capability assumptions used by Western philosophers in a simple matrix of three sets of two choices each. Most Western philosophers make fundamental assumptions in their "lens" that we can grasp in terms of this simple matrix. For example, some philosophers like Thomas Hobbes argue that mankind is essentially materialistic and in need of a strong leader to address their needs. Some, like Jean-Jacques Rousseau argue that mankind over time is essentially concerned with the needs of all. Some, like Jeremy Bentham, argue that humankind can reason through its general welfare by using rational thought, including analysis. Others, like Edmund Burke, argue that such large matters are beyond rational human inquiry and

that such decisions need to rest on appeals to historical traditions. Twentieth-century liberals and nineteenth-century conservatives argued that government could be a positive instrument to direct society. Still others, like twentieth-century conservatives and nineteenth-century liberals, argued that government cannot be a positive instrument for society.

THINKING OUTSIDE THE BOX

James Madison: Reconceptualizing the Box in the Public Sector

Although the three dimensions constitute a "box" that limits the choices of some philosophers and significantly contributes to their lenses, we need not be so limited. We can reconceptualize the matrix or box in a more sophisticated way or even think outside the box. James Madison thought within that box but he also reconceptualized the box. He decided each dimension was not a matter of one or the other, but really a mix of the two opposite view points.

In other words, Madison, as a primary author of the U.S. Constitution, assumed that in part humankind was both altruistic and materialistic. To him, the goal of the government process was to maximize the likelihood that leaders in society would make the altruistic choice. In addition, as he considered the matrix, Madison did not believe that leaders could always be either rational or incremental in their decision making, but instead he assumed that major public policy decisions were often made in some combination of the two means of decision making. In a similar manner, he assumed that government was not necessarily the sole proper or improper agent to solve society's problems, but he assumed again that a mix was often the proper solution to the challenges of living together as a society and that the mix would like alter over time.^[12]

Another option for confronting the matrix assumption of philosophers is to transcend the box entirely. For example, instead of assuming that people are either altruistically or materialistically driven, or even a mix of the two, we can assume that individual free choice can allow people to move from being materialistically driven to a higher plane of altruistic motivation. Thus, for example, people can morally improve with education and training. In this way, a whole new set of policies becomes possible and even likely with a new prescription in our lens.

Under this assumption, the concept of free choice is critical because humankind is not bound to any motivation, but can transcend to a higher plane or even fall back to a lower plane of moral development. With such an assumption, the role of philosophy is not to interfere with free choice, but rather to help

those interested to transcend to a higher plane of altruistic choice. Those that make this assumption are somewhat similar to James Madison in that they also recognize that many, and possibly most, people will still select the materialistic-driven choice in spite of their freedom to select the higher plane of moral thought. They are dissimilar to James Madison in that making people aware of that choice and helping those who want to develop morally are central beliefs of this new lens. To those thinkers, aspiration ethics, rather than conformist rulebound ethics, is critical to the development of a more advanced civilization that can better cope with the challenges of the information era.

Toward a Global Ethic

The box looks at the rational dimension of the matrix in a different way. It agrees with the nineteenth-century conservatives that complete rationality is impossible, but then also assumes, with God's help, that humankind can transcend to a higher thinking capability that somehow combines left- and right-brain thinking. For example, in this view, thinkers believe that humankind is not capable of reaching a viable global ethic with mere rational thought. However, they believe that humankind can combine rational thought with the feelings of the heart associated with the transcendent. When this is done, they believe that a significant part of humankind can accept a global ethic based on the spiritual wisdom of many of the religions of the world. Such a decision-making process can establish a universal ethic and encourage decision making using the full range of human capability. The best example of this type of reasoning is found in the work of the second Parliament of Religions and Hans Kung, in particular.^[13]

To transcend the box, one must consider the philosophic assumption of the appropriate role of government in society. In the box, there is an either/or assumption. To transcend the box in terms of the proper role of government in society, we simply assume that this decision is really not important or salient to the real purpose of life. This philosophy argues that in the larger scheme of things, the role of government in society is not really all that significant and not one of the major appropriate questions for philosophy to address. Transcendent thinkers maintain that what is salient is the care each person and each group of persons takes in others and in nature. Both government and private action can and should manifest that caring. They argue that the key is human caring and not the instrument used to manifest that caring. What is the proper mix is a function of culture and the programmatic contextual situation that each set of government leaders must decide in their own time and circumstances.

RETHINKING PHILOSOPHY

The Twenty-First Century Lens

Philosophy is a collection of lenses of understanding that helps people to realize the fundamental solution for society's problems is primarily a matter of getting people to think of themselves as interconnected. When that is accomplished, government is sometimes the solution and sometimes the problem, depending on contextual situations that change with the times and the place. To the transcendental philosophers, the answer to the government dimension is not a constant "yes" or "no," but rather "it depends." That answer transcends the box.

Is a philosophy that transcends the box possible? The answer is "yes," and it existed in its fundamental form since the beginning of recorded history. The common spiritual wisdom literature (that is found among other places in the Holy Scriptures of the Hindu, Jewish, Buddhist, Christian, and Islamic traditions) provides the basis for developing a twenty-first century philosophy. Humankind need only understand and apply that literature to develop a lens of understanding suitable for the new century. For example, the *Koran* uses the metaphor "blind" and says, "Momentous signs have come to you from your Lord. He that sees them shall have much to gain, but he who is blind to them shall lose much indeed."^[14] In other words, we are continually given signs and messages (lessons) from God. Unless we learn those lessons with our hearts, we will remain blind and unable to update the lens by which we understand life. The scriptures of all traditions teach us that government is not the answer to society's problems, but rather the answer is individually and collectively within each of us.

Moving from the abstract to the practical application is always the most difficult aspect of developing a new philosophy. What would such a philosophy mean to public administration? To the maximum extent possible, society would need to minimize judgmental behavior and maximize positive supportive altruistic behavior. Certainly, materialistic and ego-driven behavior would exist. However, under this new philosophy, when such behavior caused harm to other individuals and nature, leaders and society would either discourage or when necessary curb such negative behavior to protect people and nature. This new philosophy creates social goals to minimize divisiveness among groups, and to maximize supportive behavior of individuals and groups that supported the whole of society. However, it also paradoxically encourages individual self-development and expression.

Making decisions using this philosophy would be significantly different. This new philosophy would encourage individual use of their total mental capabilities,

including their intuitive sense of righteousness as manifested in virtue ethics. Most significantly, this new philosophy holds that improving the total person must include both the right and the left brain. Under such a new philosophy, possibly the following best defines the importance of the total mind: "Everything has mind in the lead, has mind in the forefront, is made of mind. If one speaks or acts with a corrupt mind, misery will follow, as the wheel of a cart follows the foot of the ox. Everything has mind in the lead, has mind in the forefront, and is made by mind. If one speaks or acts with a pure mind, happiness will follow, like a shadow that never leaves."^[15] Following this philosophy, part of professional training and education is global ethics applied to the work context so that administrators are well equipped to exercise their professional judgments through their responsibilities.

Under this philosophy, government is merely an instrument that is ultimately of secondary importance. Policy makers and public managers would need to consider themselves in their governmental roles as radically less significant than their roles as humans. Their primary purpose in life is their own spiritual development and their service to their fellow human-kind. This philosophy does not stress status or power of the administrator, but rather the central role of their total growth as a person in service to others. With such thinking, corruption does not make any sense and decisions that are meant to benefit the whole rather than one group makes all the sense in the world.

Applying philosophy in this manner is certainly not a call for a theocracy, but merely a call to look and apply the spiritual wisdom that informs all our religions. The scriptures of all traditions warn us that religious leaders are not immune to materialistic ego-driven decisions. Clearly, their claims to being religious enable them to easily abuse the special regard afforded to them by others. This philosophy is not a call to select leaders by religious tests, but rather a call to define a new philosophy that places that inner worth of the individual as being centrally important. This philosophy defines worth not in terms of religious doctrinal zeal or intolerance, but in terms of accumulated daily actions that reflect a person's continuing concern for the interests of the whole rather than the causes of one or any given group in society.

INTRODUCTION

Public authorities are often labeled oddities because of their quasigovernment approach to delivering services. They function outside the normal framework of government and are sometimes not counted as units of government by the census bureau.^[1] These ad hoc agencies are hybrids of public, nonprofit, and private organizations. They typically share some characteristics of general purpose governments (such as cities and counties), yet stand unique and separate in their own respect because they are utilized to finance, develop, and operate revenue-producing facilities and services. Public authorities establish their own personnel systems, adopt their own corporate name, make bylaws, have the right to sue and be sued, possess the power of eminent domain, exercise the discretion to establish rates and charges, are exempt from property tax, enter into agreements with other public and private organizations, and have the ability to utilize private money markets. In general, public authorities are a form of special purpose governments. That is, they are typically formed to deliver a specific service as opposed to multiple services. Like special districts, public authorities come in all shapes and sizes. Their characteristics vary depending on the services they deliver and the federal or state legislation from which they were created.

Public authorities have become influential in the United States, operating at the national, state, and local level and performing almost every public service imaginable. They borrow more in the tax-exempt bond market than state or local governments. The authorities have the ability to bypass debt and taxation limits that state and local governments are often subjected to.^[2] They are powerful economic and political institutions that control trade, shipping, waste disposal, and transportation in most major cities. Increasingly, authorities are utilized as conduits for intergovernmental grants and aids. They have been justified as a mechanism to rescue ailing industries, promote regional economic development, and subsidize private industry.^[3] To some, public authorities are viewed as undemocratic institutions that are insulated from the

electorate. Others criticize them as being heavy borrowers created to provide better access to capital markets.^[4]

SCOPE

For the most part, public authorities are major governmental players frequently ignored by public policy and public administration research. However, such “peculiar animals,” in the words of Doig, are more common than one would think.^[5] According to a study by Leigland, there are over 7000 public authorities in the United States.^[6] In 1995 alone, they issued \$75.3 billion in new long-term debt.^[7]

Estimating the number of public authorities in the United States is difficult for several reasons. First, state and local governments do not necessarily track the development and number of authorities. They are continuously created and dissolved. Second, the U.S. census bureau does not separate public authorities from special districts. Some special districts use the name “authority” in their title but have few characteristics of public authorities. Likewise, some special districts do not use the word “authority” in their title but have characteristics of an authority.

Some scholars argue that a public authority is by definition a corporate entity.^[8] Dimock and Dimock suggest that most state and local government corporations are called authorities.^[9] A number of other scholars do not find corporate status to be a key characteristic of public authorities.^[10] The matter is further complicated when organizations, such as those by the Council of State Governments, use such terms as “public authority” and sometimes “special district” generically to apply to classes of entities with similar characteristics, regardless of particular names given to these entities in enabling legislation. The generic use of such terms results in confusion when what a state government calls a “special district” is labeled a public authority by a social scientist. For example, Walsh, Doig, and Gerwig all exclude, by definition, from their studies of public authorities the quasi-government organizations that have taxing power.^[5,8,11]

Yet, by 1982, 23 states allowed some type of entities formally identified in state statutes as authorities to levy taxes. The argument is often made that districts and authorities can be distinguished from one another on the basis of financing methods, that districts levy taxes (and sometimes issue general obligation bonds) and authorities issue revenue bonds and are prohibited from levying taxes. Gerwig claims that the power to issue revenue bonds is a “major distinguishing characteristic” of public authorities.^[11] Walsh maintains that most special districts do not borrow heavily. This generic use of terminology is awkward because it means that a majority of states have somehow applied the name “special district” to entities that are in reality public authorities.

HISTORY

The British Parliament created the first “modern” authority in 1909 when London’s ports were consolidated into a financially sufficient organization. The Port Authority became known for its financial security and the continual development of facilities.^[2] The progressive movement inspired the use of public authorities in the United States as a way to “depoliticize” administrative operations for the management of bridges, parks, ports, and other infrastructure. Ideally, they were constructed to separate politics from administration just like the city manager form of government. They were advocated over traditional governments because their structure incorporated business practices and expertise and have their roots in the managerial approach to public administration.^[12] The first authority established in the United States was the Port of New York Authority in 1921. Later, the Port Authority was renamed the Port Authority of New York and New Jersey. This spurred the development of other port authorities along the East Coast. A second type of authority emerged with the creation of the Tennessee Valley Authority during the Great Depression. Public authorities flourished after this. They include policy areas such as economic development, education, utilities, environmental protection, health, housing, marine services, public facilities, and transportation. There are also multipurpose authorities that implement two or more public policies. They can behave similar to general purpose governments. The majority of these are located in the northeast, particularly in Pennsylvania.^[2]

PUBLIC AUTHORITIES AND STATE ENABLING LEGISLATION

As pointed out in the previous section, public authorities are defined differently depending on whom one

asks. However, since most public authorities are a form of local special purpose governments, they are typically enabled by state law. Therefore, state enabling legislation plays the key role in defining the parameters of public authorities. Quite simply, without legal permission to form, public authorities cannot exist. So what one state defines as an “authority” may differ from another, and therefore it is difficult to construct a uniform workable definition throughout the United States. Because there are 50 different states, there are as many different sets of law governing local authorities.

For example, in North Carolina, public authorities are defined by the Local Government Budget and Fiscal Control Act (LGBFCA). All monies received or spent by local governmental agencies must be budgeted, disbursed, and accounted for in accordance with the Act. The LGBFCA defines two types of public authorities. The first type has, like a unit of local government, three distinguishing characteristics: 1) it is a municipal corporation; 2) it is not part of the state’s budgeting system; and 3) it does not have the power to levy taxes. The second type has five distinguishing characteristics: 1) it is not a municipal corporation; 2) it is not part of the state’s budgeting system; 3) it has no power to levy taxes; 4) it operates on an area, regional, or multiunit basis; and 5) it is not a part of the budgeting and accounting system of a unit of local government.^[13]

ASSESSING PUBLIC AUTHORITIES AS A FORM OF GOVERNMENT

Public authorities can be considered a subset of special districts, the fast-growing form of government in the United States. For this reason, they can be viewed as one of the largest contributors of governmental fragmentation since the Great Depression.^[14] They have flourished as a form of local government, particularly in the South, because they have the fiscal advantage of shifting fiscal responsibilities for a costly function(s) to alleviate or stabilize pressures on the finances of other local governments. They are also a way for local governments to expand their revenue sources, particularly in urban areas. Cities and counties can also be constrained by the failure of state governments to equip local general purpose governments with the fiscal powers that allow them to cope with urbanization. The creation of public authorities allows local governments to get around state constitutional and statutory restrictions on taxing and borrowing powers.^[15]

Governmental fragmentation in the United States has both benefits and costs. It produces allocational efficiency, allowing residents to vote with their feet and choose their tax price. As mentioned, efficiency arguments can also be rooted in the progressive belief

that separation of politics and administration promotes efficiency that other governments do not possess. Public authorities have the ability to operate more like a business and can ignore electoral politics of other types of special districts and cities and counties. Other efficiency advantages for area-wide authorities include the achievement of economies of scale.^[16]

Governmental fragmentation has also been criticized for producing inequities among localities. However, area-wide public authorities can be a more equitable system of financing a particular service and may provide for more even service provision in a particular region than the traditional city or county. A public authority is often needed to solve region-wide problems, such as pollution or traffic congestion where a lack of cooperation exists among municipalities. They can be created for a single purpose and encompass an area in which cities and counties cannot stretch beyond their traditional boundaries to solve a problem, and political barriers exist to develop an inter-local government agreement on providing and financing a particular service.

In terms of accountability, adding another special purpose government in a metropolitan area further complicates matters by adding yet another governmental entity. Citizens often do not understand who is accountable for the services authorities provide. As public authorities have similar powers to state and local governments, but are typically politically insulated from elections, they are seen as undemocratic, inequitable, and unresponsive to citizens.

However, critics claim that public authorities enjoy too many freedoms from the rules and regulations affecting general purpose governments and that they should be controlled or effectively managed by parent governments or oversight bodies. Over the years, various types of these entities have been accused of inherent policy biases.^[8] Others have accused authorities of subverting the economic preferences of voters because they are not controlled directly by the electorate.^[17] Several public authorities have also come under fire for financial mismanagement and inefficiency.^[15]

CONCLUSIONS

Public authorities as a type of special purpose government remain one of the fastest growing forms of government in the United States. They share the features of both governments and businesses, and are responsible for providing and financing a myriad of services such as providing public transportation, regional economic development, and public housing. Their unique hybrid structure insulates and exempts them from the normal restrictions imposed on other

local governments and firms. This gives them the ability to operate in a more flexible and often desirable manner. Yet they are not without their critics. Public authorities are often viewed as undemocratic, unresponsive, and beholden to special interests.

After reviewing the definitions, costs, and benefits of public authorities as a public policy institution, a pressing question remains. How can outside accountability be increased without compromising the flexibility, independence, and efficiency required to conduct a business-like organization? The answers to this question are important and require more research because public authorities play an integral role in the policy process in the United States. They are powerful quasigovernment institutions that influence the implementation of economic and social policy. Public authorities affect how millions of Americans receive services such as mass transit, housing, and provide power. In the future, we can expect public authorities to continue to expand in numbers, increase the amount of money they borrow, and expand into new policy areas such as the justice system and welfare system. Yet there are few studies in the area of public authorities and policy implementation. There is also little emphasis on education and training of public authority managers in the field of public administration. In fact, we do not know much about these organizations and who manages them. As Mitchell reminds us: "Research on how to effectively control authorities is important for improving the legislative oversight process."^[2] This is critical to understanding accountability of these quasigovernmental institutions.

Public Budgeting, Politics in

Irene Rubin

Division of Public Administration, Northern Illinois University, DeKalb, Illinois, U.S.A.

INTRODUCTION

Public budgeting is intrinsically political. Budgeting is necessarily political for numerous reasons. The demand for public projects and programs always exceeds the supply of dollars, so there is always choice involved in any budget. Someone's request will be honored; someone else's will be cut back, ignored, or delayed into future budget years. Some degree of prioritization must take place, even when revenues are relatively plentiful, which means a process must be in place to make those allocation decisions, criteria must be used to make those decisions, and decision makers are going to have influence on those decisions. Similarly, taxes and fees must be collected to pay for public services, which means that decisions must be made about how that burden will be distributed, that is, on whom the burden will fall. Decisions on spending and taxing can be made more openly, with more public participation, or more secretly, between governmental and non-governmental elites with little accountability to the public. In a democracy, the budget is a prime tool for public accountability. In that role, the budget process may function well or poorly.

Budgetary politics results in series of tensions between technical neutrality and political policy, between ideology and pragmatism, between concerns for institutional processes and requirements and short-term partisan gains, between across-the-board and targeted allocations, and between openness to all and openness to a few wealthy individuals and interest groups. How these tensions can be resolved, whether the right blend can be achieved, and whether, if achieved, it can be maintained over time, are all highly problematic. Each budget cycle, each step in the budget process, reveals a continuing struggle.

A satisfactory balance between these tensions helps to implement democratic processes, fosters accountability, and efficiently allocates public money to the solution of collective problems. If the balance shifts too far in one direction, the result can be gridlock, technocracy, or domination by wealthy interest groups, with massive citizen distrust of the public sector. Budgetary processes may encourage movement toward the extremes, with increasing negative consequences over time. Those negative outcomes eventually force

the process back toward the middle and may restructure the budget process itself.

MEANING OF POLITICS IN BUDGETING

The word "political" is used in different ways. Political sometimes means partisan, loyalty to political parties in their efforts to win elections and determine policy. In this sense, politics suggests credit taking and blame shifting across parties. It may secondarily imply party platforms, campaign contributions, and paybacks for those contributions. Partisanship is most obvious at the national and state levels, but also functions at the local level, although often detached from national level politics and sometimes not tied closely to Democratic or Republican party politics but to local versions of parties and platforms.

In another use of the word, political refers to the policy goals of elected officials. It refers to the issues of interest to the elected officials, the problems they focus on and try to address, symbolically or practically. In the sense of policy goals, politics implies a widely discussed dichotomy between policy formation and policy implementation, and the division of responsibility between elected and appointed officials in coming up with policy proposals and shaping them during implementation.

Politics is also used to refer more broadly to the process of articulating and resolving the conflicts between priorities of different segments of society. Among the decision makers are ideologues, both appointed and elected, who have strong opinions about particular solutions or class outcomes, and pragmatists and compromisers, who try to keep the level of conflict down, providing something for everyone, and working to keep all parties feeling like they have an effective voice in government. The process of interest articulation and satisfaction maybe more open, with widespread and easy access, or it may be relatively closed, with a markedly uneven playing field that in no way approximates democratic participation. Open conflict may be encouraged or suppressed.

These three views of politics all come into play in public budgeting. They manifest themselves in five

main tensions. The first is between political policies and technical and professional neutrality. The second is between political partisanship and institutional requirements, the processes necessary to keep the institutions of government working. The third is between ideology, class politics, and symbolic politics, on the one hand, and pragmatic approaches and conflict reduction, on the other hand. The fourth is between incrementalist or across-the-board solutions and more targeted approaches, implying prioritizing and trade-offs. The fifth is between more democratic or open processes and more elitist or closed decision making. This last one emphasizes the degree of access of citizens, interest groups, elected officials, and professional staff and bureaucracies.

Policy Versus Professional Neutrality

The policy goals of elected officials sometimes clash with proposals and analyses coming from professional staff in budget offices and department or program heads. With respect to budget offices, elected officials have policy preferences they want to see implemented in the budget and want the budget office to include those preferences in the budget proposals and, if necessary, reduce or reject proposals that do not conform to these policies. For their part, budget staff want to present unbiased analyses and recommend funding for the legitimate needs of agencies or programs, even if they sometimes do not mesh with the policy priorities of the elected officials. The clash between departments and elected officials may take the form of politicians micromanaging departments or departments framing policy issues in such a way that elected officials have little say.

Compromise would suggest that major policy priorities be accommodated, but that important requests coming up from departments, including new initiatives, also be given serious consideration. Sometimes either the departments dominate to the exclusion of political priorities or political priorities dominate to the exclusion of departmental needs. Most of the time, the balance between bottom-up and top-down budgeting is closer to the middle, but may shift over time.

In recent years, the top-down policy orientation of the federal Office of Management and Budget has dominated over a more bottom-up approach. To the extent that the legitimacy and respect granted to budget examiners comes from their detailed program knowledge and ability to recognize when a proposal is necessary and appropriate, when they lose that expertise, the budget examiners become mere implementers of policies determined by elected officials.^[1]

Although elected officials may want the budget office to be responsive only or primarily to their policy

concerns, the office must maintain some degree of neutrality to function effectively and credibly. It must not become so allied with one elected official or faction that it ceases to be acceptable to a successor, or in the legislature where several parties may be present simultaneously, acceptable to both at the same time. The entire budget process hangs on the quality of revenue estimates, and numerous policy issues, such as the size of tax reductions or tax increases, hang on the estimates of the size of deficits or surpluses. If these numbers are seen to be distorted to suit policy preferences of one elected official or group, the entire process may break down.

The result is a tension between pressure from elected officials to come up with particular policy analysis and recommendations, and counterpressure from the budget and other staff offices to maintain a necessary level of professional integrity. The budget and staff offices may yield at some times to extreme pressures, and at other times, revert to more professional modes of analysis. Politicians may intensify pressures at some times and back off at others, or “go shopping.” Shopping means looking for the budget or policy shop that will come up with the desired analysis or recommendations. As a result, much budget information is slanted, putting a premium on budget analysis that is not slanted or is minimally slanted toward given policy outcomes. Gaining and keeping a reputation for such neutrality can be a major strategy for heads of budget and policy research shops.

Three examples illustrate the pressures involved, and how some budget and data provision agencies have responded. One involves the General Accounting Office (GAO), a second the Congressional Budget Office (CBO), and the third the Bureau of Labor Statistics (BLS).

The GAO is a watchdog group for Congress. Over the years, it has generated some of its own projects and responded also to congressional requests for studies. In response to intense antagonism on the part of many in Congress to the agency and deep budget and staffing cuts, the GAO cut back its self-generated studies to almost nothing, working only on Congressional requests. Because the GAO responds more to the committee chairs than to the ranking minority members, it disproportionately serves the agenda of the majority party in each house. Thus, it has positioned itself closer to the end of the continuum of policy responsiveness than professional independence. However, it has also devised for itself a prioritization scheme so that it can still act independently on issues it deems crucial. The history of the agency suggests that the proportion of self-generated studies has varied, and will continue to vary in the future, but it was least able to do independent studies during a period of intense threat to its staffing and resources.^[2]

The CBO performs various functions for Congress, including estimating the costs of bills, the impact of bills on state and local government, compliance with budgeting rules, and estimates of the growth of the economy. It is also responsible for estimating and tracking the size of the deficit or surplus. Many Republicans in Congress endorsed a policy of large tax reductions and wanted the CBO to determine estimates of the deficit or surplus that would support such a proposal. To tweak the estimates of the growth of the economy necessary to push up estimates of the surplus, they pressed the CBO to adopt some form of dynamic estimates, that is, estimates of the positive effects of tax cuts on the growth of the economy and hence the growth of revenue. Modest assessments of such effects are included in the president's budget proposal and in Congress's budget resolution, but these legislators wanted to exaggerate the effect because they wanted to adopt a particular policy. They pressured CBO in various ways to get a larger number. These pressures included appointing a head of the office who would support dynamic estimates and legislating a requirement that CBO offer Congress dynamic estimates. Although there was no agreed-on methodology for estimating dynamic effects, the CBO complied by increasing the estimates of the fiscal dividend, the economic stimulus that was supposed to result from a balanced budget. These numbers kept going up, and then began to come back down. The CBO put the estimates into its reports as Congress demanded, but also put its own estimates into its reports, arguing that its own figures represented a more likely outcome. Congress ended up deciding on a process called directed scoring, taking the estimates of the CBO or the OMB, whichever it liked better. The CBO thus maintained its reputation for integrity but lost some of its influence over decisions, as Congress took whichever analysis fit its policy preferences most closely.^[2]

The BLS is located in the Department of Labor. Its responsibilities include the collection and reporting of various statistics on business and the economy. One of its tasks is to regularly update the Consumer Price Index. Because many of the pensions that the federal government owes, including social security, are indexed to the Consumer Price Index, a slower rate of growth in the index would reduce spending and help to balance the budget. During the years of massive efforts to balance the federal budget, this strategy seemed like a politician's dream, a way of cutting expenses without taking any responsibility for doing so. The problem was that the BLS was jealous of its reputation for professional integrity and refused to amend the index without the appropriate level of research to justify the changes. Some members of Congress wanted the changes quickly, regardless of the underlying research, and were willing to use a range

of pressureful tactics to get their way. Those tactics included convening an "independent" commission (the Boskin commission) to estimate the "true" rate of inflation, threatening to take the decision out of the hands of the agency and to cut their budget.

Responding to Federal Reserve Chairman Alan Greenspan's observation that reducing the index would make it easier to balance the federal budget, Speaker of the House Newt Gingrich tried to force quick changes on the BLS. "This weekend, when asked about [Alan] Greenspan's comments, the Speaker of the House said that he would give the Bureau of Labor Statistics people '30 days to get it right'^[13] or he would fire them and give the job to the Fed." Gingrich's position was that if BLS did not revise the index downward quickly—presumably without technical study—they would lose the responsibility for making the changes. He would give the job to the agency or organization that agreed with his policy position. Mr. Gingrich reportedly threatened to cut the BLS out of the budget if it did not make the changes in 30 days (Congressional Record, Senate, January 18, 1995, Page S1125).^[2] In the end, the BLS did gradually revise the index downward, not by as much as the Boskin commission recommended, but substantially. The agency continued to do the underlying research to adjust the index, asking for more money to do the research, but it was not clear that the agency was examining sources of increased inflation as well as decreases.

The history of the BLS indicates that the agency has been subject to political pressure, but that those periods have given the agency a determination to resist that pressure, stay out of the political limelight, and focus on neutral analysis. In this case, however, the BLS was unable to avoid a policy controversy. It did what it could to maintain its professional status, but probably did not come out completely unscathed. Relative to the level of pressure it was enduring, it remained fairly strong and independent, helped by a structure that granted its commissioner a long-term insulation from political pressures.

These three cases indicate that maintaining professional neutrality can be a struggle and agencies succeed more or less at different times. However, gaining a reputation for independent analysis and not following policy dictates gives an agency an extra importance. Some agencies find that there is little to be gained by yielding to political pressures and that they do best by standing tall. If they are taken out of the decision-making loop, at least they can come back another day with their integrity intact. However, if it looks likely that elected officials will make good on some of their more extreme threats to the agency, it may have little choice but to cave in on that issue, for the time being.

Although the relations between budget or data offices and political officials suggests that agencies and the whole decision-making apparatus are better off if the staff agencies are allowed to maintain their professional independence, the situation may be different in the relationship between elected officials and line department or program offices. Sometimes the requests coming from the programs and departments are technical, but sometimes they are policy related or geared to the survival and growth of the agency. On the one hand, the Defense Department bitterly resents the intervention of legislators in their business, dictating particular weapons systems or particular companies or locations for acquisitions, but, on the other hand, it may itself propose weapons and contractors with the idea of winning support from legislators who are from particular states or regions affected by the contracts. The elected representatives may engage in legitimate policy making or less legitimate micro-management, whereas the agencies may engage in technical implementation or independent policy making, thus bucking congressional priorities. Absence of a reasonable balance is likely to generate conflict until a better balance can be achieved.

In Kansas City, Missouri, the budget office and departments were relatively strong with respect to the elected officials. Their position was generally that they were operating with marginal and inadequate budgets, doing the best they could, and that any further guidance or cuts from the political officials were unacceptable. They did not trust the elected officials to make the right decisions or to see matters as they did. They reportedly made most of the policy decisions themselves, without informing the elected officials, informing them after the fact, or offering them alternatives that represented a narrow range of options, including the one they wanted and some other completely unacceptable choices. Elected officials, led by the mayor, resented being excluded from major budgeting and allocation decisions, and thus ordered a study of the process and requested recommendations for changes that would include them in more meaningful ways. The Kansas case reinforces the idea that, if the situation becomes too unbalanced, pressures will develop to reestablish a more satisfactory distribution of policy-making power.

Partisanship Versus Institutional Loyalty

Partisanship means loyalty to party or faction, as opposed to loyalty to processes or the institution as a whole. This division applies to both staff and elected officials. Partisanship means efforts to win short-term gains to look good to the voters and to make the other side look bad. It is often associated with symbolic

stances that appeal to a particular faction of voters. These symbolic stances may be extreme, be resistant to compromises, and represent unworkable solutions to problems.

Snow and Willoughby discussed the distinction between partisan staff and staff who work for the whole organization at the state legislative level.^[3] They argued that the staff who work for the whole organization deal with issues that affect the whole institution and its prerogatives. The example they give is of a governor who is proposing to merge numerous line items. Such a merger is likely to enhance the decision-making power of the governor vis-à-vis the legislature. The institutionally oriented budget staffers would keep abreast of this issue and call it to the attention of the legislators.

Partisanship in Congress is sometimes in direct opposition to the requirements for the institution to function smoothly. One extreme example of partisanship, as opposed to institutional requirements, occurred in the federal government in 1995/1996 when neither political party was willing to vote for a budget compromise, shutting down the federal government, which is not allowed to spend money unless there has been money appropriated for it. Institutional requirements allow for compromises and passing the budget in a timely way each year; partisan concerns may seriously interrupt that flow. Other examples have occurred when legislation was included in bills by reference, resulting in huge bills with major content that legislators did not have time to read and which were described in the text for examination and discussion.

Joe White illustrated the tension between partisan concerns and the requirements for routine passage of legislation in his discussion of earmarking in the appropriations committees in Congress. He argued that normally appropriations committees take into consideration the interests of the minority as well as the majority party in the distribution of pork or earmarked spending, but that the leadership, which is intensely partisan, often presses for more exclusive distribution of pork and earmarks for the majority party members in key districts for key elections. Appropriations committee members know that the earmarks will not survive unless there is a coalition on the floor to pass them, and hence pass around the earmarks to create that majority, a requirement that generates a certain amount of civility. If they award pork more exclusively along party lines, they risk losing their own pork by riling up the opposition who have nothing to lose from attacking.^[4]

In recent years, partisanship has often created a kind of brinkmanship that prevents timely passage of the 13 money bills that are supposed to pass by September 30 of each year and encourages budget

tricks that thwart the intent of the rules. The credibility of the process suffers as a result.

in recent years, Congress has been unable to complete all of them, resulting in last-minute deals that evade, break and ignore spending caps called for in the budget resolution by resorting to various budgetary devices, such as designating large amounts of spending as “emergency” spending.

“Once you go down the road of winking and nodding through the process, you erode the credibility of the process,” says Richard E. May, a principal at Davidson & Co. and a former Republican staff director of the House Budget Committee. The last-minute haggling results in helter-skelter lawmaking, one analyst argues. “Lately, the closing days of the session have deteriorated into a very costly and unstatesman-like cross between a food fight and a game of budgetary chicken in which the aim of each side seems to be to inflict maximum political embarrassment on the other while getting as much as possible for one’s own spending or tax priorities,” Martha Phillips, former executive director of the Concord Coalition, a group that advocates fiscal restraint, told the House Rules Committee earlier this year.^[5]

Budget staffer Bill Dauster called attention to various procedural rules violations in the mid-1990s, after a major influx of ideologically motivated Republicans. He argued that such violations occurred because the Republicans sought short-term, partisan advantages. His list of rules violations included removing the standing rule to limit conference committees to same subject sent to the conference.

To secure last-minute passage of a version of the Federal Aviation Authorization Act that included an extraneous provision of special interest to the Federal Express Corporation, the Senate voted 56 to 39 to overturn the Chair and nullify the subject-matter rule. Now small groups of Senators, like the five men who sat on the conference committee on the FAA bill, can add any new matter they please. Now, Senators have no recourse if the conference committee exceeds the scope of what the Senate committed to it. In Senator Kennedy’s words: “They will acquire the power to legislate in a privileged, unreviewable fashion on virtually any subject. They will be able to completely bypass the deliberative process of the Senate.”^[6]

Dauster listed numerous other serious procedural changes engaged in for short-term partisan gain. Then he quoted Senator Kennedy’s warning about the change in conference reports:

This . . . is a vote about whether this body is going to be governed by a neutral set of rules that protect the

rights of all Members, and by extension, the rights of all Americans. If the rules of the Senate can be twisted and broke and overridden to achieve a momentary legislative goal we will have diminished the institution itself.^[6]

Dauster concluded:

This past year, the Republican Senate majority has thus repeatedly arrogated greater power to the majority to use fast-moving legislative trains to move unrelated matters of its choosing. This majority has thus repeatedly torn down the protections that the Senate affords minorities. This majority has shown a disturbing willingness to cast aside long-held precedents and institutions to serve immediate policy ends. That, then, is the unifying theme that runs through the procedural actions that the Republicans took last year and that they seek to take this year. The Republican Senate stands ready to sell its birthright for a mess of pottage. It shows contempt for the institution. It focuses solely on the immediate political gain.^[6]

An article in *Govexec* underscored several recent budget gimmicks used to circumvent legitimate and necessary budget rules. Some of them were evasions of budget caps probably agreed to by both parties, but some seem to have been used for partisan gain.

Back in 1995, Republicans tried to insist that the Clinton administration submit a budget that would be certified as balanced by the Congressional Budget Office. The administration argued that a balanced budget certified by the Office of Management and Budget should have been good enough. Now, OMB appears good enough for Republicans—sometimes. Using “directed scoring,” budgeteers are able to choose which office scores certain programs. This allows Congress to choose either CBO or OMB estimates—whichever office says the program costs the least. House Democrats charged earlier this year that Republicans used at least \$14 billion of OMB scoring in determining the costs of programs. “They’re using two sets of books, but they’re not telling us which set of books they’re using on what occasion,” Obey charges, adding that, “One day it’s the OMB. One day it’s the CBO. One day it’s the Wizard of Oz.”^[7]

Another procedure absolutely necessary for the intelligibility of the process is the use of baselines. Baselines allow participants to see whether budget allocations are going up or down.

There are disagreements as to how baselines should be calculated, but as long as there was technical disagreement over relatively similar baselines, the results were easily interpretable. But the argument became partisan, with some advocating baselines that included inflation and others baselines that excluded inflation,

avored agencies' baselines were calculated differently than other agencies, and the result became muddled to say the least (refer to Ref.^[8]).

Some analysts argue that the partisan and short-term gains will always win out when pitted against the longer-term institutional and process requirements, but the negative consequences of eroding comity, delaying decisions, and continuous finger pointing sometimes have the effect of shifting the balance in the other direction. Many of the procedures that Dauster saw falling by the wayside lasted many decades, providing evidence that process requirements have a kind of vitality of their own. Partisan fights may dominate for periods at a time, and then die down.

Ideology Versus Pragmatism

Partisanship does not necessarily imply ideological or symbolic stances. Advancing party interests may involve passage of legislation and compromises, as well as credit taking, blame casting, and brinkmanship. But in budgeting, as in politics more broadly, elected officials are sometimes interested in ideological positions and/or symbolic stances rather than compromises and legislative solutions to problems. Such stances are likely to exacerbate conflicts. Although partisan squabbles seem like street fighting, ideological battles mobilize followers in ways that may seem more like wars.

In issues of taxation, those who are taxed make demands on politicians to reduce their taxation. That can be done either across the board, for everyone, for the wealthy at the expense of the poor, the poor at the expense of the wealthy, or for selected smaller groups or individuals who have negotiated political access. Some of these proposals may take on an ideological tone. Tax cuts across the board are expensive, reducing the revenue available for expenditures, and thereby increasing the size of deficits or shrinking the scope of government. The latter has been a goal of conservatives for some time. Democrats try to shift the burden of taxation more to businesses and the wealthy, Republicans more away from the wealthy onto the middle and lower classes. Ad hoc sets of exemptions can add up to considerable revenue losses, and because achieved through the progressive tax structure at the federal level, often provide disproportionate benefits to the well to do.

Citizens for Tax Justice, a respected, left-of-center advocacy and research group, charged that "profitable corporations that will receive a total of \$7.4 billion in immediate Alternative Minimum Tax (AMT) rebates if the economic 'stimulus' bill recently passed by the House of Representatives becomes law are also major campaign contributors, giving \$45.7 million to federal elections since 1991." The organization charged that

"these companies and others use campaign money to manipulate the political process to win huge tax breaks unavailable to ordinary Americans."^[9] Citizens for Tax Justice tried to make a case that these tax breaks were class based and not available to individuals.

Some political candidates and elected officials have argued for a flat tax at the federal level, ending the graduation that results in wealthier people paying a relatively higher tax burden than poorer people. In the United States, some have graduated incomes taxes, whereas others have flat taxes, showing a distinctly different profile of class politics.

Ideological and symbolic positions have been important in campaigns to balance the federal budget, as some elected officials supported proposals for a constitutional balanced budget amendment. Many of the supporters of such an action wanted to combine it with revenue limits in an effort to reduce the scope of government. This position can be considered an ideological one, rather than a more technical one requiring budgets to balance. When the budget was finally balanced in 1998, ideologues had to shift to buying down the debt to keep the pressure on government to reduce spending and the scope of government.

The line between pragmatic approaches and ideological ones can be overdrawn, there is a point at which an accumulation of smaller, less symbolic legislation may well add up to an ideological platform, but there are differences. Ideological stances need to be pure and clear, and hence avoid many of the compromises necessary for passage. Pragmatic approaches may be so compromised or so counterbalanced by broad distribution of benefits that their ideological content is lost.

Incrementalism Versus Tradeoffs

Incrementalism refers to a kind of across-the-board allocation, in which each department or program gets a proportionate share of additional revenues available to be spent. Incremental approaches avoid conflict, eschew policy concerns, and are not really about uncovering or solving collective problems. They work best when there is a steady but moderate increase in revenues and the existing allocations reasonably match public expectations and concerns. They function less well in more constrained revenue situations, where trade-offs are necessary, and some criteria for making the trade-offs is often desirable.

Because revenue is constrained, the stress between the relative comfort of incremental allocations and the relative pain but increased efficiency of targeted cuts is often apparent. A common form of budgeting at state and local levels is called target-based budgeting. In target-based budgeting, the central budget

office and the chief executive officer give a target (a maximum) for the request from each department. These requests are set in such a way that the combined total of the requests will be lower than expected revenues, creating a pool of resources, within tight constraints, for reallocation. The process of making the cuts in each program requires some kind of prioritization, and the allocation of the savings also requires some kind of prioritization. The possibility exists of cutting one department a bit and giving more to another, changing the budget priorities to match policy shifts, but this opportunity is often not taken seriously. The power of the departments puts enormous pressure on the central budget office to continue to support them much as they always have. There is some prioritization within departments, but not usually much reallocation between departments. Prioritization may take place in some circumstances, but the fallback position, the more comfortable position, is a more across-the-board approach.^[10] Some who use target-based budgeting have suggested that there is a constant battle to prevent it from becoming just another incremental budget allocation technique.

Trade-offs—increasing spending on one department or program and reducing it elsewhere—occur in every budget to some extent, but such trade-offs become more visible when there are tight, widely publicized ceilings on expenditures. Trade-offs may occur without much prioritization, however. At the national level, when the federal budget was constrained by the spending caps on the discretionary side of the budget (from 1990 to the period of budget balance beginning in 1998) trade-offs were made frequently, but they were framed by the committee structure and by departmental programs. Secretaries were told that, if one expenditure was increased, then they had to make reductions somewhere else to stay under the caps. Appropriations subcommittee members could not raise the spending of one department under their jurisdiction without reducing the spending of other departments in their jurisdiction. What became relevant was the jurisdictions of each subcommittee, which in some cases did not represent a logical set of comparisons. Moreover, the caps called for limits and hence offsetting reductions, but did not require any criteria for prioritization or any formal prioritization process. Some agencies experienced budget cuts because they were less popular than the other programs in a subcommittee's jurisdiction. If they been compared with other departments or programs, they likely would have fared better.

That is not to say that budgeting never involves formal or informal prioritization, only to say that it is likely to occur only at intervals or at the margins. Some communities do a form of zero-based budgeting that incorporates a list of priorities and compares proposals with that list. Others require council or board members

to state for each program how important it is to them to expand it, contract it, or keep it the same.

Open or Closed Decision Making

The process of budgeting itself is laden with politics, as decision makers jockey for power to determine increases or decreases. One key element of that process is its openness to individual citizens and interest groups. Ideally, the process is open to citizens who can express their priorities and see them incorporated into the budget. They should also get to see the results of their spending in accounting reports and performance reporting. Because individuals may not have the time or knowledge to participate directly and because the federal government is removed in space from most citizens, this citizen involvement may be indirect, through various interest and advocacy groups. However, openness to such organized groups may or may not add up to democratic participation, depending on the openness of the decision making to all interests or only some. If interest groups primarily buy their influence, then poorer groups are likely to be left out. Elected officials are interested in votes as well as money, so they may remain open to smaller and poorer groups if they represent a major constituency group, but those with more money may at times be granted more access.

From the point of view of political power, the question has to do with the levelness of the playing field—does each group have the same kind of access to budgetary decision making? One attempt to make the playing field less level was called the Istook amendment (there have also been numerous variations of the Istook amendment). After much opposition from the not-for-profit charities who would have been hurt by it, the measure failed. Its goal was to prevent not-for-profit groups and charities, which had received federal funds lobbying government or influencing programs. Because not-for-profits have to apply for tax-free status and show that they are not lobbyists, they have to record their lobbying efforts and keep them below a fixed level. Those requirements can be made more burdensome and confusing or less so. The more burdensome, the more difficult for smaller organizations to have any input on the legislation that designs and funds the programs they run, normally at considerable savings to the public.

Advocates for the non-profits described how this proposed legislation would affect them:

Nearly every charity pointed out that service delivery and advocacy go hand-in-hand. The Catholic Community Services in Salt Lake City, Utah, feeds over 500 people a day in their homeless shelters, receives federal grants, and views itself an advocate for homeless

families. The Vermont Public Transportation Association provided over 420,000 trips to doctors' offices and hospitals, receives federal grants, and views itself an advocate for seniors and those with disabilities. The Big Brothers/Big Sisters in Delaware receives a combination of federal and state grants for a variety of projects including one to establish a mentor relationship between volunteers and children from single-parent families. Yet they, too, are active in advocating on youth issues, including child abuse.

But because the Istook Amendment is so technical and confusing, they would be afraid to do any advocacy. One senior citizens group in Michigan, run by an 85 year old man, said he could not even understand one provision in the Istook Amendment that dealt with the definition of an "affiliated organization"—yet he knew he was covered. And with the "bounty hunter" provision that allows anyone to sue a federal grantee for up to 10 years for alleged non-compliance, most charities are fearful they will be sued—even when trying to faithfully comply.^[11]

In the case of the Istook amendment, there was an intentional effort to make it more difficult for those providing services to the poor to advocate for their clienteles or programs. Although Istook was followed by numerous others, all the efforts failed. The results are less optimistic though when looking at tax policy, where it seems clearer that big contributors get more than their share of tax breaks, and get far more back in tax dollars than they spent in campaign donations. In this area, it seems that the playing field is not level. Supporters of this system would probably argue that they are the ones being taxed, so naturally they are the ones who need the tax relief. Still, because the benefits are tailored to big contributors, there are others who would want and maybe need tax relief who do not get it.

Joe White presented this tension between representing everyone in an open fashion and representing only organized interests with money in his discussion of interest groups and the appropriations committees. He favors the side of openness when discussing earmarks or pork allocations:

A former House subcommittee chair expressed this preference well when he commented that, "I think there is a sense of accomplishment on the part of a member who is approached by constituents—generally it is local government types, the town council, the school board, the airport authority—who have a problem and they think federal money will help... If it's wasteful, if it's not wanted, they'll hear about it... if you do an \$800,000 innovative housing project, it won't change the face of that town. But it tells the town, 'we think what you're doing has merit, it might be seen as a model.'" So the member and the

community both feel pretty good. They had a specific need, brought it to Congress, and it got fulfilled. It says the system works, their voice is heard in a faraway place called Washington, and it got done. And that's representative government.^[4]

White's interviewees argued that it was not only constituents who stood to gain jobs who caught legislators' attention, but also the local elites. Further, White argued that legislators want to feel good about a project, feel that they have done something good. White concluded that "passion can be a relevant resource for interest groups: the intensity of demand can affect the legislator's sense that meeting a demand is doing good." Based on White's interviews with legislators, budget processes and decisions are open at the level of earmarking of funds on appropriations committees. At the national level, one would expect decision making to be less open on decisions about priorities and overall program funding.

At the state and local level, much effort has gone into including the public in budget planning activities and goal formation, but this responsiveness appears to be cyclical. In Phoenix, the city manager reported that the city had alternated between domination by business interest groups and broader public participation. He offered the explanation that the business domination, when it occurred, was too extreme and set off a reaction among the public who felt unrepresented.^[12]

CONCLUSION

Politics in budgeting can best be viewed as a series of tensions, which may be reasonably balanced or become seriously unbalanced, with major consequences. Elected officials may be denied their legitimate right to determine policy; monied interest groups may buy their way into less fair distribution of government benefits, thwarting democratic processes; budgets may be slow to adapt to changing priorities; and short-term partisan advantages may disrupt processes and institutions, leading to massive public distrust. Political scientists need to pay more attention to what leads to imbalances, which budget processes encourage excesses and which curtail them, and how to reestablish balance once it has dissolved into acrimony and exclusiveness.

INTRODUCTION

For those who agree or disagree over the assumptions and policy implications of the public choice approach, one item remains non-controversial—public choice uses the economics methodology to study politics. The theoretical perspective of public choice uses economic principles to understand political organization and practices, covering matters of constitutional design, rational actions of politician and citizen, voting mechanisms, resulting policy outcomes that affect the provision of public goods, and the bureaucrat's role in government. Public choice theorists examine the political market as the public sector's equivalent institution for the private market. How governments allocate resources to provide goods and services to its citizens is a collective decision-making process. The shaping of this collective decision-making process is where public choice theorists focus their attention. How institutions are involved at each level of this process is the primary concern of public choice theory. Although the focus is on institutions, at the center of public choice theory is the individual; from government to political parties, every decision-making unit is composed of individuals.^[1]

ROLE OF THE POLITICAL MARKET

The political market is necessary to provide goods that the private market cannot produce because of the nature of the good. Public goods hold special characteristics of non-exclusion and non-rivalness. The first characteristic refers to the impossibility of excluding the consumption of a particular good by others, leading to excess demand. For example, a lighthouse benefits all boats, and the owner of that lighthouse cannot exclude one boat from its beam. Similarly, a non-rival good is one that, in the process of consuming or using it, does not change or alter the ability of others to consume or use it. Thus, free riders will accompany a non-rival good because a person can consume this good without ever paying for it. An example of a non-rival good is a web site where many people can view the content at the same time, as long as the server does not

become congested from too much traffic. These two characteristics present problems for private market production, and because a failure in production or consumption exists in the private market, public goods result from this failure.^[1]

Public choice theorists refer to these private market failures as externalities and consider externalities to be the major reason for government intervention into the private marketplace. An externality occurs when a decision or action of one person benefits or harms another such that the market price does not reflect the true costs of these actions. Public choice examines why this externality exists and attempts to address the problem through the analysis of producer's and consumer's property rights. Many problems arise during such analysis: property rights are often not clearly defined; the liability for the costs and benefits is unclear and does not affect one set of decision makers; and the externality often affects a large number of entities. Thus, public choice suggests that it is the government's role to define and enforce property rights when it is feasible, and where some resource may become extinct. The policy instruments used for definition and enforcement, from auctions to taxes and subsidies, are debated in regard to the costs that government intervention imposes on the market. However, although most economists identify private market failure and the existence of externalities as a reason for government intervention, Tullock cautioned that government involvement and the instrument used to combat an externality also produce externalities. "We are choosing between two imperfect instrumentalities. Unfortunately, that choice [among instruments] is a government decision, and [this decision] will also generate externalities."^[2]

The political market not only affects the government's role in externality cases, but it also affects the production of public goods. This production occurs within numerous governmental institutions, which in turn impacts how government will know what public good to produce—from quantity to quality. The influence of each decision and how that decision is made can result in inefficiencies. Public choice uses the principles of private market efficiency to guide the development of political market theory that addresses matters and problems such as public good production, externalities, and the absence of property rights.

HISTORY

Although many recognize Buchanan and Tullock's *Calculus of Consent*^[3] as the beginning of public choice, the genealogy can be traced to Adam Smith's *Wealth of Nations*.^[4] Smith focused on the nature and causes of the wealth of nations, specifically the efficiency of government expenditures.^[1] This was the old political economy. Throughout the centuries, economics and political science developed separately until the mid-twentieth century. The works of Black, Arrow, and Downs refocused economists on political issues.^[5–7] However, *Calculus of Consent* was the first work to explicitly integrate two economic elements—economic modeling of utility-maximizing behavior for political choices and the understanding of politics as an exchange similar to the private market.^[8] Buchanan and Tullock's book led to the formation of a journal entitled *Non-Market Decision Making*, which later evolved into *Public Choice*.

In the ensuing 40 years, two main schools of study have evolved: constitutional political economy and the theory of bureaucrats. Buchanan remains tightly bound to the former, and this course of study is often referred to as the Virginia School. This school emphasizes classical political economy and examines the effects of institutions and structures. The latter area of study examines both the normative and empirical aspects of bureaucratic theory. The Chicago School is most associated with the empirical aspect, focusing on three distinct ideas. First, bureaucrats, like all other individuals, are indeed utility maximizers such that they will support policies that convey the greatest individual benefit. Second, citizens are also rational utility maximizers and seek the greatest personal gain, denoted as methodological individualism. Third, institutional service arrangements are more efficient if multiple, smaller scale units exist. The first and the second ideas are in direct contradiction of public administration theory, which presents the bureaucrat as serving the public interest best through Wilsonian-influenced, centralized, service delivery units.^[9] Through public choice's two major schools, public choice theorists have addressed numerous political issues at all levels of government. The remaining sections examine some of the most prevalent issues.

CONSTITUTIONAL ECONOMICS AND GOVERNMENT INSTITUTIONS

In the vein of Buchanan's work, public choice from a constitutional political economy perspective questions the outcomes of the political market by examining the origins of government. The argument is that the choice of constitutional rules will define the available

choices within a constitution—operational decisions such as the size of the education or defense budget.^[1] Thus, constitutional rules are the institutions that shape a government's response to society and the efficiency of that response.

A constitution's framework also affects the composition of government and determines how politicians can represent and address their constituent's concerns. Politicians use political party platforms to appeal to voters, and individual desires form an aggregate impact on politicians through voting mechanisms and the actions of pressure groups. Finally, within government, politicians work for legislation that is beneficial to them. In the eyes of a public choice theorist, these events do not proceed without private interests outweighing public interests. Each event entails decision making in the political market. The voting rules, enforced to permit the mixture of majority and minority preferences, create further problems and biases. For example, government may gain greater discretionary power because of the incentives for rational ignorance—that it is in an individual's best interest to remain ignorant of particular issues because the costs of gaining information is greater than the benefits received. Such political market failures result because the institutions that exist are unable to allow citizens to express the intensity of their preferences for public goods.

With government as the producer of public goods and citizens as the consumers, rational actors represent both sides of the political market. Just as for bureaucrats, public choice holds that citizens have preferences for the provision of public goods, demanding a specific quantity, quality, and desired mix of these public goods. The central problem in the political market is how citizen preferences are realized and expressed. Public choice holds that only efficient government institutions will enable the conveyance of this information such that government will produce the appropriate amount and mix of public services. Thus, the institutions and mechanisms established to gain information from citizens are the intellectual fodder for public choice theorists, and especially for those constitutional political economy theorists. A general contention is that the mechanisms—from voting, representation, referendum, and opinion polling to political party platforms—do not enable individual realization of preferences, nor do they efficiently reflect individual preferences in a collective way. The political market is also at the mercy of impediments that also affect the private market. Information is not perfect or free, so individuals rationally abstain from trying to understand political debates and candidate positions. Coupling this with political parties in which one candidate represents multiple political issues and inefficient voting systems, public choice theorists

believe that the mechanisms must provide lower costs to the voting citizen.

The concern for efficient mechanisms leads to another prominent issue within public choice theory—rent seeking. Within economics, a rent is the amount paid for a resource that is fixed in supply in both the short and long term. Wealth is accumulated from this resource because its supply is restricted, particularly if market conditions are not competitive. Rent seekers desire government regulation that promotes barriers to entry, and they will engage in activities that use numerous resources inefficiently. Rent seekers employ the time and other resources of law, marketing, and financial experts to lobby for favorable government legislation. Public choice desires better constitutional rules and institutions to minimize rent-seeking activity. Consequently, as in the case of externalities, public choice theorists desire the most efficient mechanism, acknowledging that all mechanisms will entail other inefficiencies.

THEORY OF THE BUREAUCRAT

Constitutionally defined governmental institutions do not alone influence policy creation. In fact, a large part of public choice theory examines the bureaucratic implementation of policy within government and its agencies. Although public administration and political science prescribes that bureaucrats seek the common good or public interest as civil servants, public choice holds that bureaucrats are rational individuals that will pursue policies that are personally and professionally beneficial. As utility maximizers, bureaucrats will use their power to enlarge agency budgets, giving them larger perquisites as a complement to the static, civil servant income. These bureaucratic actions lead to resource waste and rent seeking.^[3,10] Johnson stated that “the source of bureaucratic problems lies not in the bureaucrats but in the nature of public goods and the incentives, controls, and institutions existing in the bureaucracy.”^[1] He identified several primary causes of bureaucratic inefficiencies. The first is the loss of administrative control because the legislature intervenes between the bureaucracy that produces the goods and the citizens who consume the goods. The other causes result in the bureaucracy producing more public goods than demanded. This excess supply is a result of bureaucracies facing no competition in providing public goods. The political market gives bureaucracies few incentives to be efficient, so the tendency is toward budget maximization, not minimization.^[1,10]

Given this view of bureaucrats, how public goods should be produced is of great concern to public choice theorists. Focusing on local governments, the perspective calls for multiple, smaller-scale operations rather

than the Wilsonian-dictated, centralized, consolidated delivery mechanisms. This conclusion is a direct result of public choice criticisms of Wilsonian ideals. Public choice theorists believe that market competition results in more efficient distribution of the preferred mix of services because public service provision is labor intensive and lacks economies of scale. In addition, natural coordination among service units is superior to formal structure.^[9] Public choice theorists have conducted numerous empirical studies examining the outcome of jurisdictional, service delivery consolidations to determine if evidence supports this predicted outcome; the results are mixed as Lovrich and Neiman’s work suggests.^[9]

Although public choice is contentious to those in political science and public administration, many recognize the importance of questioning bureaucratic activity. Jackson stressed the importance of questioning “whose interests are served by the policy, which interests dominate the process and why.”^[11] Inefficient government institutions lead to bureaucratic failures, and public choice addresses these failures by proposing changes to the rules and incentive structures in bureaucracies.

GOVERNMENT ACTION

The application of private market principles to the political market and combining that with economic methodology has provided a rigorous framework to analyze the government’s role in society. Public choice theory seeks to improve government decision making through the minimization of bureaucratic tendencies and rent seeking. Public choice recognizes that every action has multiple costs associated with it, and understanding the political market consequences of the selected instrument associated with such government action is central to making decisions about whether particular goods should be publicly provided; and if public, which instruments best minimize the costs and externalities in the political market.

Not surprisingly, viewing government through the lens of public choice naturally leads to conclusions that government is often too large, too wasteful, and too inefficient. Such conclusions are often more in line with politically conservative positions and policies. However, those who would characterize public choice as “antigovernment” often miss the point. It is not the goal of public choice theorist to limit government for the sake of ideology. Rather their point is that the choice for government contains its own set of externalities, and the institutions and mechanisms chosen can be selected to minimize these externalities. One must always recognize that interventions may be more costly than the externalities themselves.

Green Bay, Wisconsin, U.S.A.

INTRODUCTION

In the eighteenth and nineteenth centuries, the study of politics and political economy overlapped in many important ways.^a By the early twentieth century, however, the disciplines of political science and economics had become quite distinct. The two disciplines differed in their focus of inquiry, the assumptions they made about individual motivation and in the research methods employed. Political scientists studied actors in the political arena, and economists studied actors in the marketplace. Moreover, political scientists tended to assume that political actors pursued the public interest, and their concerns were strongly normative. In distinct contrast, the fundamental behavioral assumption of neoclassical economic theory is that economic actors vigorously pursue their self-interest and the focus of inquiry is positive. Finally, the two disciplines were sharply divided with respect to methodology. Economics became increasingly deductive with heavy emphasis on mathematical modeling. In sharp contrast, political science retained its tradition of verbal argument and inductive empirical methods.

Beginning in the late 1940s and greatly accelerating in the 1960s, the chasm dividing the disciplines of economics and political science began to close in significant ways with the emergence of the subfield within the discipline of economics called *public choice*.^[1]

The subject matter of public choice is the same as that of political science: the theory of the state, voting rules, voter behavior, party politics, the bureaucracy, and so

on. The methodology of public choice is that of economics, however. The basic behavioral postulate of public choice, as for economics, is that man is an egoistic, rational, utility maximizer.

In brief, public choice economists use neoclassical theory “to study voters as rational maximizers, politicians as entrepreneurs, and bureaucrats as suppliers in a market-like process of consumption, production, and exchange.”^[2]

In retrospect, the emergence of public choice theory can be seen as a natural progression of social science. The competitive market economy is one basic kind of social choice mechanism relating to the allocation of scarce resources through various market exchanges. By the mid-twentieth century, economists had developed good knowledge of how the decentralized decision making, information, and incentive structures of a competitive market economy worked. Under certain conditions, albeit highly restrictive, an efficient allocation of resources would result. That is, the dollar-votes of consumers for alternative private goods and services would be efficiently channeled to producers and made effective. Competitive pressures would force those producers failing to produce in line with consumer demand, and at least cost, out of the marketplace. Relatedly, various defects or failures of market allocation also were increasingly recognized and gave rise to a large literature on the theory of market failure focused on such topics as imperfect competition, public goods, and externalities.

Moreover, by the early 1950s, it was increasingly recognized that the political process should be viewed as a social choice mechanism that in important ways complemented the market mechanism. Indeed, the failure of market allocation to achieve various social goals, equity, as well as efficiency, provides a natural explanation for the emergence of political institutions.

KEY TOPICS OF PUBLIC CHOICE

Nobel laureate Kenneth Arrow’s pathbreaking work *Social Choice and Individual Values* (1951) gave rise to a large literature examining the aggregation of individual preferences to maximize a defined set of

^aThis article is largely based on two sources: Mueller, D.C. *Public Choice II*; University Press: Cambridge, 1989; and Miller, G.J. The impact of economics on contemporary political science. *J. Econ. Lit.* 1997, 35 (4), 1173–1204.^[1-2] More basic sources include: Peacock, A.T. *Public Choice Analysis in Historical Perspective*; Cambridge University Press, 1992; Mueller, D.C. *The Public Choice Approach to Politics*; Edgar Elgar: Brookfield, VT, USA, 1993; and Tullock, G. *Government: Whose Obedient Servant?: A Primer on Public Choice*; Institute of Economic Affairs: London, 2000. Two strong critiques of public choice theory are the following: Green, D.; Shapiro, I. *Pathologies of Rational Choice Theory*; Yale University Press: New Haven, CT, USA, 1994; and Cullis, J.; Jones, P. Public choice: outrageous theory and enraging tests? In *Public Choice Analysis of Economic Policy*; Chrystal, K.A., Pennant-Rhea, R., Eds.; St. Martin’s Press: New York, 2000; 59–90.

normative criteria. Important topics of Arrow's work include the so-called "voting paradox," when majority rule is used to decide issues.

A concise example of Arrow's voting paradox is as follows:^[3] Assume a community of three individuals A, B, and C who are considering three alternative levels of public expenditure: \$10 million, \$5 million, and \$3 million. What Arrow showed is that even though each individual voter's preferences for alternative spending levels may be consistent, the community's preferences may not be. Specifically, in a series of paired elections to determine the socially preferred level of expenditure, an election between the \$10 million level and the \$5 million level, the \$10 million level may win by a 2 to 1 vote. Likewise, in an election between the \$5 million level and the \$3 million level, the \$5 million level may be chosen by a 2 to 1 vote. Finally, in an election between the \$10 million level and the \$3 million level, it may happen that the \$3 million level wins by a 2 to 1 margin. Such a majority rule outcome clearly is inconsistent. The first election suggests that the community prefers the \$10 million level of expenditure to the \$5 million level. The second election suggests that the \$5 million level is preferred to the \$3 million level. Standard notions of consistency thus imply that the community prefers the \$10 million level to the \$3 million level. The third election, however, suggests that the community prefers the \$3 million level to the \$10 million level. It must be stressed here that majority rule need not necessarily lead to inconsistent decisions by the community. The possibility clearly exists, however, especially when the issues decided collectively are multidimensional. That is, the choices do not correspond to more or less of a single characteristic, such as alternative spending levels. And when majority rule fails to result in consistent decisions, such problems as agenda manipulation and voting cycles emerge (i.e., paired voting can go on forever without a determinate outcome).

Arrow's work stimulated much research on real-world procedures for aggregating the preferences of individual voters under alternative voting schemes. Consequently, a significant literature exists on public choice in a direct democracy, that is, where social choices are decided directly via voter referenda. Key issues of this literature are the general question of the choice of voting rule, and investigations of the properties of specific voting rules such as the unanimity rule, the simple majority rule, and various alternatives to the simple majority rule. Closely related is the literature on local government finance and expenditure examining the so-called Tiebout hypothesis.^[4]

In the mid-1950s, Charles Tiebout advanced an important hypothesis with respect to the provision of local public goods such as education and refuse collection. He hypothesized that in urban areas with

a large number of independent political jurisdictions, households would vote with their feet and choose to reside in the jurisdiction with the bundle of local public goods and related taxes that they most preferred. Under a set of restrictive assumptions, Tiebout postulated that an efficient public goods and tax price equilibrium would emerge. Tiebout's provocative hypothesis has stimulated a considerable theoretical and empirical literature on the financing and provision of local public goods.

An even more important area of analysis is that of public choice in a representative democracy. The vast literature in this respect has been stimulated by Anthony Downs' classic work, *An Economic Theory of Democracy* (1957), probably the single most influential public choice work on the discipline of political science. Key concerns of this literature include the positive and normative aspects of two-party and multiparty competition as well as the effects of wealth-maximizing special-interest groups on political outcomes. An important line of research in this respect is the so-called "rent-seeking literature" that focuses on how special-interest groups (e.g., farmers, trade unions, industry associations as well as various professional groups such as physicians and lawyers) attempt to use government to transfer income to themselves. One well-known means is the erection of various international trade barriers to protect domestic industries and their workers from foreign competition.^[5]

Another major subject of public choice analysis is the supply of government output by government agencies and enterprises. While many social scientists have analyzed government bureaucracies, Niskanen was the first to use neoclassical economic theory to rigorously model the behavior of a government bureau.^[6] A key implication of Niskanen's model is that government bureaus will attempt to maximize their budgets, and in doing so, will produce an inefficiently large output. Niskanen's analysis is controversial and has been difficult to test empirically. Some evidence, however, from the peculiar Oregon school budget referenda process, supports the budget-maximizing hypothesis.^[1]

Public choice modeling also has been applied to the analysis of politics on key macroeconomic outcomes as well as the size and growth of government. Key topics include the effects of politics on short-run business fluctuations, the so-called political business cycle. Relatedly, the influence of special-interest groups and their redistributive activities on long-run economic growth has been investigated. Finally, a significant public choice literature exists, examining alternative hypotheses concerning the rapid growth of governments in the twentieth century, in particular, in the high-income welfare states of northern Europe.

PUBLIC CHOICE: A BRIEF OVERVIEW OF THE EMPIRICAL EVIDENCE

Are key predictions of public choice models supported by credible empirical research? A single, clear-cut answer cannot be given in this respect. Certain predictions are more strongly supported than others. For example, broad and rigorous evidence now exists that, in general, government suppliers are less efficient than private enterprise (see also *Enterprise: Public versus Private* in this Encyclopedia). For example, Mueller presented a listing of some 50 studies examining comparative enterprise efficiency.^[1] In only two studies were government enterprises found to be more efficient. In over 40 studies, government firms were found to be higher-cost producers, often some 40–60% (or more) higher.

A second important public choice hypothesis is that advanced by Mancur Olson in *The Rise and Decline of Nations* (1982). Olson argued that most interest group activity is focused on distributional goals that raise the satisfaction of their members. A key macroeconomic implication is that “distributional coalitions slow down a society’s capacity to adopt new techniques and to reallocate resources in response to changing conditions and thereby reduce the rate of economic growth.”^[1] Mueller concisely examined several studies that provided reasonably strong empirical support for Olsen’s theory.^[1]

Finally, key empirical facts to be explained by a credible theory of government are the large cross-national differences in the size of government as well as the rapid growth of government in the twentieth century, in particular, in the welfare states of northern Europe. Several supply-side and demand-side hypotheses have been put forward to explain the size and growth of government. A major study testing the relative strength of alternative hypotheses is the study of Switzerland by Pommerehne and Schneider.^[7] Commenting on this study, Mueller noted:^[1]

Pommerehne and Schneider’s results forcefully demonstrate what may be regarded as the single most important message that public choice has to teach—namely, the rules of the game *do* affect the outcomes of the game. Institutions matter. In Switzerland, the more direct the citizen influence on political outcomes, the smaller is the scale of government. Among the developed countries, citizens of Switzerland are able to exercise control over government more effectively than anywhere else. Only Switzerland makes much use of direct democracy and the referendum, and it has the strongest federalist system in the world. It also has the smallest public sector among the developed countries. The results of Pommerehne and Schneider suggest that these facts are related.

LIMITATIONS OF PUBLIC CHOICE MODELS

Clearly many public choice hypotheses are supported in some measure by existing empirical research as well as real-world experience. One must stress, however, that the straightforward application of neoclassical economic theory to the political arena has been only partial successful. Many important predictions emanating from public choice models have not been well-supported empirically. Indeed, in a major recent article on public choice theory, Miller argued that the greatest value of the incursion of public choice economists on political science is that it has stimulated the development of the subfield of “positive political theory” that seeks to build equally rigorous models that better explain real-world politics.^[2] Miller wrote:

[T]he most unambiguously beneficial effect of economics on contemporary political science has been methodological... Downs, Arrow, Olson, and others not only brought a new rigor to a theory-starved discipline, they had the prestige of micro-economics behind it. After all, the rationality assumptions worked to explain markets; why should political actors be less rational than other humans? It was necessary to come up with an equally logical deductive argument from equally reasonable first assumptions that led to empirical predictions that were somewhat closer to the world as political scientists could measure it. The casual, verbal argument, supported by selected case evidence, was no longer sufficient to carry the day....

Substantively, the contributions of economists have also been significant. Contrary, to the original intent of Downs, though, the contribution of economics was not simply to reveal the mechanistic, market-like underpinnings of the political world. Modern political economy is not simply an adjunct to market analysis, in which smooth exchanges are made between producer/politicians and consumer/voters via market-like competition and some political substitute for a price mechanism....

On the contrary, the most powerful impact has always been from the puzzling paradoxes revealed first by economic analysis, rather than from any predictable patterns revealed.

Miller developed his argument at length by focusing on four central topics of contemporary political economy: individual voting and electoral participation; the aggregation of voter preferences; the aggregation of decentralized voter information in a world of imperfect and costly information; and the influence of institutional constraints on political actors. To illustrate the contribution of positive political theory, we turn to a brief discussion of the theory of public goods, or more broadly, the theory of collective action. Based on the parsimonious assumptions of neoclassical economic theory, one would predict severe impediments to the provision of a public good (e.g., national

defense) or the attainment of a group goal requiring member contributions. If all group members are assumed to be rational egoists, then a basic incentive problem, the free-rider problem, would seem to arise invariably. Each person acting in their self-interest will not voluntarily contribute to the provision of a public good (or group goal), anticipating that others will contribute, and that the public good will be provided to their benefit but without their contribution. If all members of the group, however, are rational egoists, then none will contribute, and collective action will fail.

This basic prediction flowing from neoclassical economic theory, however, is not well supported by the huge number of public goods experiments that have been undertaken in recent years as well as much real-world experience. For example, Ostrom outlined key findings strongly supported by the existing body of experimental research and which are at considerable variance with the zero contribution thesis outlined above. Key findings here include the following:^[8]

1. Participants in public goods experiments are found to contribute 40–60% of the resource endowment given them in support of collective action to provide the public good.
2. When participants believe that others will cooperate, they are more likely to cooperate.
3. As participants learn the game better, they tend to cooperate more, not less, as rational egoists would be predicted to do.
4. Face-to-face communication tends to increase cooperation.
5. How much group members contribute in a public goods experiment is influenced by contextual factors (e.g., allowing communication among members, assigning sanctions against noncontributors, etc.).

On the basis of the above findings, Ostrom argued that a revised theory of collective action consistent with the empirical evidence is one that assumes two kinds of “norm-using” participants in addition to rational egoists. The first she labels “conditional cooperators,” that is, individuals willing to initiate cooperative action when they believe others will reciprocate. The second kind of “norm-using” participant she labels as “willing punishers,” that is, individuals who will use permitted sanctions to punish noncontributors to the public good (or group goal).

A less radical approach to explaining collective action is to retain the assumption that individuals are rational egoists but assume that an individual's satisfaction depends, at least in part, on an individual's acceptance and standing as defined by a relevant group relationship. Miller illustrated this point using the

example of participation in the U.S. civil rights movement of the 1960s:^[2]

[M]ost protestors in the civil rights movement did not decide to participate as individuals, but as members of local churches with highly structured systems of social incentives that linked good standing in the group with participation in the civil rights movement. And a common denominator of the research on voting, interest groups, and public goods is that much of the variation in individual behavior has to do with how an individuals relevant group has defined the social costs and incentives associated with those acts of political participation.

It also should be stressed at this point that the discipline of economics and public choice theory have had a major impact on political science via the emergence and rapid growth since the mid-1970s of the partially related subfield called the “new institutional economics.” The two central propositions of this new subfield are, first, that “institutions do matter” and, second, “the determinants of institutions are susceptible to analysis by the tools of economic theory.”^[9] In particular, concepts such as “transaction costs” and “credible commitment” have been used by economists and positive political theorists to explain key institutional features of real-world political systems and why they change over time.^[10] In this context, Miller noted:^[2]

[T]he anomalous and paradoxical behavior revealed by [the application of economic theory to politics] forced political scientists to pay attention to the structured institutional constraints on individual maximizing behavior. Understanding political participation indicated that individuals did not make atomistic choices in a structureless environment, but responded to blandishments shaped by the social structures of which they were a part.... It was only my focusing analysis on the institutional determinants of voting, legislative, and regulatory behavior that anomalous behavior began to be understood....

As the force of political institutions was revealed, the emphasis in economic modeling shifted subtly from the determinants of the self-interested choice, to *restraints* on self-interested choice. Increasingly, institutional analysis focused on what came to be known as the “commitment” issue—settings in which long-term gains could be achieved by limiting, rather than expanding, the scope of individual choice.

CONCLUSION

The application of neoclassical economic theory to politics has clearly contributed in a substantial way to an improved understanding of political institutions and outcomes. It is also the case, however, that many

key predictions, in particular those fundamentally emanating solely from the rational egoist assumptions of neoclassical economic theory, have not been well supported by empirical research. A credible case can be made that the primary long-run impact of neoclassical economics on the study of political institutions and behavior is the emergence of the new field of positive political theory that has led to a richer, more varied understanding of politics:

[C]ontrary to the early economists in political science the most powerful determinants of outcomes are not the atomistic maximizing choices of individuals, but the groups and institutions that guide and constrain self-interested individual choice. Our understanding of the anomalies generated by the first generation of political economic analysis has propelled political science (and perhaps economics!) to understand the rich and compelling social norms and institutional contracts that govern political exchange in its diversity.^[2]

Public Funds Investment Strategies

William G. Albrecht

Department of Political Science and Public Administration, University of North Carolina at Pembroke, Pembroke, North Carolina, U.S.A.

INTRODUCTION

In 1939, John Donner, Manager-Secretary for Los Angeles California's Department of Pensions, published an article titled "Investment of Pension and Other Trust Funds" in which he detailed two personal observations. First, he indicated that the question of investing monies with both safety and income in any type of financial organization was a problem challenging the ingenuity of the best minds. Second, he noted that the prime requisite being followed by government trust funds was safety of principal; the extent of income was considered secondary. In terms of management, Donner's conclusion was that investment techniques were incapable of substituting for the deductive ability and experience of a seasoned administrator.^[1]

Retrospectively speaking, Donner's early 20th century commentary on public sector investment practices resembles the adage "the more things change the more they stay the same." While the field has evolved in terms of constraints, goals, and objectives, the persistent constant is that the question of investing monies with both safety and income remains a 21st century problem challenging the ingenuity of the best minds. This statement is supported with the acknowledgement that those working in the discipline continue to encounter increasingly sophisticated techniques and unorthodox proposals for handling the nation's finances. In recognition of these facts, the essay presented here broadly defines and illustrates public sector investment strategies while outlining relevant factors for public organizations operating in the modern era.

INVESTING PUBLIC FUNDS

Any contemporary discussion concerning public sector investment practices must begin by realizing that public funds are collective monies segregated by a mechanism known as fund accounting. The intent of a fund accounting system is to control the purpose of financial resources while illuminating sources and uses of funds. Although a complete delineation of fund structures varies by organization, the most relevant aspect pertaining to the investment of public monies

is the proximity of the relationship between a fund's liquidity requirements and operating budget decisions.

Future operating budget decisions are important factors in determining disbursements and the need for liquidity or "cash" at a particular point in time.^[2] Furthermore, the results of investment decisions contribute to underlying patterns in cash flows. Funds susceptible to operating budget decisions require a predictable short-term investment focus and generally fall under the purview of cash management. A government's general fund is an example of a public fund with cash management characteristics. Funds less sensitive to these same decisions afford administrators the prospect of pursuing investment opportunities requiring a longer term focus. Trusts are the most straightforward illustration of these types of funds.

The fundamental justification for investing public funds is the economic notion that money has a "time value." The premise of the time value concept is that an amount of money is worth more in the present than some future period if the money is invested to produce a "yield." Yield^a is referred to with a variety of labels including "interest" and "rate of return." Whatever the designation, the common element is that each term refers to what an investor receives over and above the principal amount invested.^[3] Given that public organizations operate in a world of scarcity a higher yield on invested monies is preferred to a lower yield.

A corollary to the time value of money concept is that there are opportunity costs in the form of foregone revenues associated with an organization's failure to invest idle funds.^[3] Sustained increases in average price levels are also capable of eroding the purchasing power of monies not employed to keep up with inflation. In both cases the economic consequence is that an organization's capacity to disburse benefits, internalize safety margins, replace existing assets, expand services, or reduce reliance on future contributors is, in all probability, compromised.

The counterpoint to an attempt at capitalizing on the time value of money notion is that such activities introduce a degree of uncertainty in relation to the

^aTechnically, the specific definition of "yield" is dependent upon the type of investment and underlying monetary flows.

future value of the original or “principal” amount invested. In finance uncertainty is commonly called “risk.” Like yield the term risk is referred to with a variety of labels including default risk, market risk, and liquidity risk.^[2] Whatever the designation, the common element is that each expression refers to the possibility of a loss of investment income or principal amount.^b

Compared to yield the existence of scarce resources implies that organizations prefer less risk to more risk. Combining this preference with that for a higher yield suggests that managers of public funds face the task of generating a yield on invested monies while reducing uncertainty. Consequentially, investment strategies often focus on making decisions within the confines of these two constructs. However, every administrative choice of approach must necessarily be tempered by two realities. The first is that achieving a higher yield generally entails the acceptance of increased risk. The second is any course of action involving public funds must consider nuances underlying the public sector.

DELIMITING PUBLIC FUNDS INVESTMENT STRATEGIES

Drawing on the discussion above, a public sector investment strategy may be defined as a public organization’s plan for using idle money in a way that increases financial holdings while protecting the principal amount invested. A subjective assessment of the literature suggests that researchers and practitioners tend to refer to these plans as well as their formulation and implementation in one of three ways: asset allocation decisions, investment process decisions, and decisions concerning combinations of asset allocations and investment processes.

Asset allocation tactics involve choices as to the placement of funds in capital market instruments or location. While the universe of possible instruments is vast most can be classified as either debt or equity. Debt is essentially a loan and includes short-term money market instruments such as U.S. Treasury bills, bankers acceptances, and commercial paper. In addition, debt investments consist of long-term instruments of the U.S. government, banks, and the bonds of various private sector businesses both foreign and domestic. As an “asset class,” equity instruments refer to stock ownership in domestic or international firms.

By definition any public organization’s choice of a single instrument constitutes a basic asset allocation

strategy as the decision amounts to an assumed level of risk and expected yield. Fig. 1 illustrates this point. As shown, Treasury bills are positioned at the low end of the risk–yield range while government and corporate bonds are located in the middle spectrum of these criteria. By comparison, domestic and international equities are at the high end of the risk–yield range. The slope of the capital market line reveals a positive relationship indicating that a higher yield is achieved at the expense of increased risk.

Collective combinations of instruments are called a portfolio. And, portfolio decisions culminate in an investment strategy with characteristics that are apart from a single instrument. The divergence stems from the concept of “diversification,” which suggests that risk can be reduced by investing in financial assets that exhibit less than perfectly positive correlation.^[4] While a complete discussion on the benefits of diversification is complicated, an intuitive feel can be achieved by recognizing that the yields of various instruments are unlikely to consistently move in directional tandem. This analogy also applies to economic sectors and economies. Thus, risk reduction is the *raison d’être* for investing public funds in a portfolio with a variety of instruments from various locations.

Compared to asset allocation strategies decisions concerning investment processes involve procedures that a public organization may choose to utilize during the implementation of investment activities. Again, while the universe of prospective processes is substantial most involve engaging in some type of purposive action. For example, in the cash management arena time period “hedging” strategies entail the *processes* of buying or selling contracts called “futures” for the *purpose* of locking in future or current yields, respectively.^[5] Futures contracts are legally binding obligations between buyers and sellers for the transfer of

Fig. 1 Relationship between risk and yield.

^bMiller^[2] summarizes default, liquidity, and market risks as uncertainty surrounding full recovery of principal value, the ability to convert to cash, and negative changes in financial markets, respectively.

U.S. securities, certificates of deposits of banks, and state and local government bonds. Options contracts are an additional type of tactic for hedging against undesirable interest rate movements. However, unlike futures contracts, options do not represent an obligation but the reservation of a right by the holder to take action at a specified time. An interesting point to note is that a combination of these hedging processes or “options on futures contracts” is also a possibility.^[5]

Another process frequently used by public trusts is that of passive indexing. When engaging in this strategy an investment manager purposively attempts to duplicate the risk–yield characteristics of a target portfolio by mimicking its construction with identical proportionate holdings of matching instruments. The term indexing also denotes the simpler procedure of investing in a “mutual fund” company that has an established portfolio resembling that of a target index. Regardless of the approach, passive indexing implies that no attempt is made to accrue risk or yield levels in excess of the market. Popular indexes used by investment managers include the well known “S & P 500” for equity investments and the “Lehman Aggregate” for debt holdings.^[6]

While an obvious relationship exists between the imitative processing strategy of indexing and asset allocation tactics there is no reason to assume that an organization pursuing an indexing strategy will do so exclusively. Instead, some may opt to engage in both indexing and active asset allocation tactics, which are attempts to achieve yields above that of market indices. Strategic decisions of this nature are based on a view of inefficient markets where additional information, insight, or skill can lead to yields that are superior to that of a passive target portfolio.^[7] Market views aside this is one more illustration of how asset allocation and process decisions can be combined to create an overall investment strategy out of subsets of strategies.

Inputs to Modern Public Funds Investment Strategy Decisions

While Donner’s conclusion regarding the non-substitutability of investment techniques for seasoned administrators with deductive ability may or may not be deemed as accurate for his time, a case can be made that they are now complementary inputs to public investment strategy decisions. A notable reason for this assertion is that escalating levels of fiscal stress and increasingly volatile markets have combined with the legislative trend of liberalizing investment statutes to create a complexity that is essentially a barrier to unaided rationalism. The result is that the administrative ability to predict has at least joined if not

superseded the ability to deduce in terms of prominence. This normative shift has facilitated the development and use of techniques designed to aid administrators in formulating competent investment decisions.

To illustrate, various formulas such as the Miller-Orr and Economic Order Quantity models can assist managers in determining optimal cash balances so that extra treasury funds may be invested in a marketable securities portfolio.^[8] Graphical procedure such as yield curves are also available for examining the relationship between the yield on various financial securities and time. Other techniques include optimization procedures that allocate trust monies to debt and equity investments within a portfolio that are “efficient.” Efficiency in this sense means that no other possible combination of instruments can provide a lower level of probable risk or a higher rate of yield.^[9] While a number of other techniques are also available the shared facet among most is that each is a purposive process culminating in a decision rule for formulating and implementing a rational investment strategy. Thus, techniques are arguably a complementary input to modern strategy decisions if not actually part of a strategy.

Public Sector Distinctions

A discussion concerning public sector investment practices would be incomplete if no specific mention were made concerning the purpose of such activities in relation to public organizations and the environment in which they are implemented. The public setting relinquishes both explicit and implied “governance” constraints that are in addition to that of fund limitations or efficiency considerations.^[10,11]

For example, public organizations exist to fulfill missions that relate to achieving social goals; the accumulation of money is not considered an end. Instead, money is deemed as a means to a mission oriented end. Investing public funds, like all financial management activities, is intended to reduce the likelihood that financial concerns come to dominate the normatively superior goal of achieving organizational effectiveness.^[12] In this sense, the mission orientation of public organizations is an explicit governance constraint on investment objectives and the formulation and implementation of strategies designed to achieve them.

Another illustration of an environmental constraint can be seen in relation to the historical evolution of legalities pertaining to the field. While the liberalization of public sector investment statutes appears to be a persistent trend the inclination is far from unfettered. Public money managers often remain bound by internal investment policies or constitutional restraints

Fig. 2 Investment strategies as intervening variables.

that limit investments to low-risk instruments in specific geographic areas.^[13] In some cases, trusts, such as pension funds, are directed to consider social or economically targeted investments.^[14] These political decisions limit the investment strategy opportunity set and confound the discharge of rational investment tactics. When these circumstances occur, public managers working in a liberal democracy must adjust strategies and techniques to account for prescribed social purposes.

An implicit constraint also exists in relation to public money managers themselves. Empirical research consistently indicates that most seek to protect investment resources against any type of loss.^[2,15] In addition, theoretical work on the acceptance of financial management techniques by public administrators suggests that managers' full definitions of risk and yield may incorporate qualitative characteristics as well as quantitative measures.^[15,16] Normative considerations aside, the reality of such occurrences is that administrator behavior potentially limits the accumulation of fund surpluses via investment strategy decisions.

CONCLUSIONS

This essay has broadly defined and illustrated public sector investment strategies and outlined relevant

factors for organizations operating in the modern era. The emerging picture is that investment strategy decisions are intervening variables between an organization's governance and resulting yield. Fig. 2 portrays this "mediating" relationship.

As shown, governance and techniques are complementary inputs to strategy choices.^c These decisions, either in isolation or combination, are then predicted to determine yield. The potential for combining asset allocation tactics with process decisions is denoted by the dashed path. In the case of such an occurrence a process strategy would *potentially* qualify as a moderating factor for asset allocation decisions. This moderating hypothesis is supported empirically with studies finding that more than 90% of the variability in a fund's yield is the result of asset allocation tactics, and that managers perceive asset allocation decisions as being the most important investment strategy. The feedback loop designates the figure as a systems model akin to Lynch's approach for analyzing budget accountability.^[17] An interesting and unanswered empirical question is how realized yield determines these precursors.^[10] The (political) environment is

^cHere governance is a generic term referring to the multifaceted complex of behaviors, rules, or practices that influence investment decisions.

depicted as an exogenous force surrounding organizations and their decisions.

An important point to note is that factors other than those mentioned in this limited space may influence an organization's choice of investment strategy. For example, fund size and professional sophistication are practical determinants for active participation in money markets.^[2] These requisites often preclude the eligibility of organizations that are unable to incur the higher transaction costs in reducing their effect. Of course, investment management practices have evolved toward diminishing such barriers through processes such as pooling and the production of professionals who specialize in modern techniques. This confirms that the question of investing monies with both safety and income remains a 21st century problem challenging the ingenuity of the best minds.

Public Goods

Cristina E. Ciocirlan

*Department of Public Administration, Pennsylvania State University at Harrisburg,
Middletown, Pennsylvania, U.S.A.*

INTRODUCTION

Public, or collective, goods are characterized by non-excludability in use, non-rivalry in consumption, or both these characteristics combined. A good is non-excludable if it is costly and counterproductive to exclude individuals from using it. It is non-rivalrous if one person's consumption cannot reduce or impede the ability of others to consume the good. When individuals do not take into account the marginal social cost of consumption, the public good becomes congested. Generally, a public good is also indivisible; one cannot meaningfully speak of units of a public good (e.g., ambient air).

When public goods are provided through collective action settings, there is a high likelihood of conflict between self-interest and group interest. This conflict leads to a prisoner's dilemma type of outcome, which corresponds to a Pareto-inferior^a allocation of goods in economy.

The inherent nature of public goods and the collective action problems can lead to the failure of markets to achieve Pareto efficiency.^b Thus, there is a justifiable role for government intervention. Legislators are faced with the problem of pricing public goods and providing the value-maximizing quantity of public goods for society.

CHARACTERISTICS OF PUBLIC GOODS

Public, or collective, goods are non-excludable in use, non-rivalrous in consumption, or may exhibit both these characteristics in varying degrees. A good is non-excludable if it is impossible to exclude other individuals from simultaneously consuming the same good. It is non-rivalrous if the consumption of one person of the public good does not impede another person's consumption of the same good at the same time. Both the consumption and the production of public goods are indivisible; public goods cannot be divided up and

sold.^[2] Public goods can often be congested or non-congested. Congestion occurs when the marginal social cost of consumption exceeds the marginal private cost of consumption.^c The divergence between these costs represents an externality of consumption. When non-excludable and non-rivalrous public goods are also uncongested, they are called "pure public goods." Lighthouses and national defense are classic examples. When these goods are congested, they are called "ambient, or impure, public goods" with consumption externalities.^d Ambient air is an example. When consumption of public goods is limited to residents of the political jurisdiction in which these goods are provided, they are called "local public goods."^[2]

In contrast, the defining characteristics of private goods are rivalry in consumption, excludability in ownership and use, and divisibility. Rivalrous consumption means that a private good is consumed exclusively by the person who buys it. If person X wears a pair of shoes, person Y cannot wear the same shoes at the same time. Excludability in ownership and use means that one has control over use of the good. One can undoubtedly decide who is allowed to drive their car. Private goods are divisible; they can be divided into units and assigned a unit price.

The public good-private good dichotomy recognizes a continuum between the two extremes. Any good exhibits one or more of the public good characteristics. When public good characteristics are found in a commodity, both the need for consumers to pay for it and the incentive of suppliers to provide it are challenged. Thus, markets tend to produce those commodities with public good characteristics in inefficiently small quantities.^e

^cThe marginal social cost of consumption is defined as the sum of the marginal costs that consumers of a public good impose on each other. When the good is uncongested, the marginal social cost is zero. The marginal private cost of consumption is the cost of consumption generated by an additional unit of consumption supported by one individual (Ref.^[1]).

^dThese goods were labeled as such by Ref.^[1].

^eThe two basic questions that could indicate whether markets could effectively provide commodities with public good characteristics are whether consumers would pay for something that would be available anyway and whether suppliers could collect from buyers the value of their services (Ref.^[2]).

^aA Pareto-inferior allocation of goods is not a socially ideal outcome because it is possible to find a different allocation that makes some individuals better off without making anyone worse off (Ref.^[1]).

^bA Pareto-efficient allocation of goods is an optimal allocation; it is impossible to find an alternative allocation that makes some individuals better off without making anyone worse off (Ref.^[1]).

When the costs of exclusion are small, but the good is non-rivalrous, private provision is possible. For instance, a private supplier could build a bridge and charge a fee for the usage of it. There are two problems with this setting, however. First, the producer might not set the price equal to the marginal cost of consumption, which is zero.^f Second, the private supplier may not provide the optimal resource size to maximize social surplus. In the presence of congestion, the marginal social cost of congestion^g becomes positive. A private supplier must charge users a price equal to the cost imposed on all other users during congested times. However, private firms would charge consumers a higher cost than the marginal social cost of congestion to generate sufficient revenues to cover the costs of construction and maintenance. Thus, the market fails because it excludes users who would obtain higher marginal benefits than the marginal social costs that they impose.

When public goods are non-excludable but rivalrous, they confront problems of overconsumption. Non-excludability translates into the failure of the market to efficiently provide open access resources. When choosing the optimal consumption quantity, individuals consider their marginal private costs instead of marginal social costs; hence, they overconsume these resources and underinvest in their preservation.^[1]

THE COLLECTIVE ACTION PROBLEM

A collective action problem arises when individuals, acting out of pure self-interest, are unable to coordinate their efforts to produce desirable public goods. In a collective action setting, there is a high likelihood of conflict between the self-interest and the common interest of members involved.^[3] Each individual attempts to free ride on others' efforts. Free riding occurs when one individual reaps the benefits of a certain action or product without paying for it. Because everyone thinks alike, no public good will be produced and everyone is worse off than they would have been had each individual contributed toward the provision of the public good. In short, collective action problems arise when individuals arise at Pareto-inferior outcomes in the pursuit of their self-interest.

The collective action problem can be illustrated with the game-theoretic terminology of a prisoner's dilemma

setting (see Fig. 1). Suppose a community confronts serious air pollution problems caused by inefficient car driving. Ambient air is the closest to the purest definition of public goods: once cleaned, it is not possible to exclude individuals from breathing it, and one individual's breathing of clean air does not reduce the ability of others to breathe it at the same time. The community decides to institute a system by which cars are driven less and only when it is necessary. It is assumed that cycling and walking are viable alternatives.

Given the perfect excludability and non-rivalry in consumption and use, an individual has a strong incentive to free ride on others' efforts to keep the air clean. Thus, the individual has two strategies available: to cooperate and drive less, or to defect and rely on others' efforts to reduce driving in the community. Community members can also pursue these strategies, depending on their valuation of clean air and the extent to which they pursue self-interest.

In Fig. 1, if the individual decides to cooperate, the payoffs are either clean air with the expense of less driving both for individual and community (when community cooperates), or dirty air at the price of less driving for individual only (when community defects). If the individual decides to defect, the payoffs are either clean air at no cost to the individual (when community cooperates) or dirty air (when community defects, too). Mathematically, if the individual decides to cooperate, regardless of what community members do, the payoff is -2 , which is the sum of individual payoffs from cells A and B. If the individual decides to defect, the sum of payoffs is 0 (the sum of individual payoffs from cells C and D); thus, the individual will choose to defect.

		Community	
		Cooperate	Defect
Individual	Cooperate	A. Clean air; less driving for both individual and community Payoff = $(-1, -1)$	B. Dirty air; less driving for individual only Payoff = $(-1, 0)$
	Defect	C. Clean air; less driving for community only Payoff = $(0, -1)$	D. Dirty air; driving stays the same Payoff = $(0, 0)$

Fig. 1 Collective action problems as prisoner's dilemma games. *Note:* Prisoner's dilemma games have been used for the first time as a conceptual framework in Ref.^[4]. The first number in parentheses represents the payoff to the individual; the second number represents the payoff to the community. Costs of less convenience stemming from reduced driving are indicated by -1 , the absence of these costs is indicated by 0 .

^fIn the absence of congestion, the cost of an additional car passing that bridge (i.e., the marginal cost of consumption) is approximately zero.

^gThe marginal social cost of congestion is the cost imposed to society by an additional unit of public good consumed. The marginal private cost is the cost of consuming one additional unit supported by one individual.

Likewise, if community decides to cooperate, the sum of its payoffs for cooperation will be -2 (community payoffs from cells A and C). If the community decides to defect, the sum of its payoffs is 0 (the sum of community payoffs from cells B and D); thus, the community chooses to defect, too. The dominant strategy is, therefore, that both individual and community defect, and the public good will not be provided.

Nevertheless, the view that collective action is undermined by private interest can be challenged on several grounds. First, in large groups, the pursuit of one individual's self-interest yields an insignificant benefit. Thus, the outcome of the larger groups may exhibit public good characteristics.^[4] Second, the formation of coalitions within organizations, facing attractive ratios of benefits to costs, could lead to optimal collective solutions. Third, altruism, gaining utility when someone else gains utility from an outcome, could lead to optimal cooperative solutions. Billions of dollars are donated every year to charitable and religious organizations.^h These organizations work toward a collective good, the achievement of which does not selectively benefit organization members. The collective outcome is a public good. Fourth, cooperation tends to be possible if social incentives—such as desire to gain or sustain friendship, maintain one's social standing, or concerns about reputation reliability and dependability—are present.^[6]

THE ROLE OF GOVERNMENT

The presence of non-rivalry, non-excludability, or congestion can lead to the failure of markets to efficiently provide public goods.ⁱ For example, if national defense were to be provided privately, all individuals in society could benefit from it, and it would not be possible to exclude or charge individuals for national defense. If everybody free rides and nobody contributes to the provision of a public good, the public good will not be supplied and everyone will be worse off.

The rationale for government intervention stems from its power of coercion and taxation. Government has the power to force consumers to contribute to the provision of the public good. Public good provision through government can be achieved by direct and indirect means. Direct provision could be performed

through government bureaus and special districts, whereas indirect provision could be done by independent agencies and contracting out government functions to private sector.^[1]

Economic theory stipulates that various levels of government produce different public goods efficiently. Local governments should produce the optimal quantity of a local public good demanded by their local citizens, whereas the federal government must supply those goods that generate benefits for people living outside the local jurisdiction. In reality, however, cities and counties are multiproduct jurisdictions; they often produce goods that spill over to other jurisdictions.

Just as markets sometimes fail to produce social value, so too can government. Political economy theories of regulation demonstrate that politicians often fail to employ the best policy instruments that would achieve Pareto-efficient allocations. This may occur either because of their capture by special interests^[7] or simply because of problems inherent in direct democracy.^[1]

CONCLUSION

The provision of public goods through private markets and collective action is inefficient because of free riding and prisoner's dilemma types of games. The intervention of government in economy is thus justified. Through its power of coercion and taxation, government is theoretically able to supply an efficient quantity of public goods. However, just as markets fail, governments can also fail. Optimal economic instruments are often not used because of the capture of politicians by special interest groups or simply because of problems inherent in direct democracy. Depending on the public good in question, partnerships between government and private firms sometimes leads to efficient outcomes.

Although theoretically it has been demonstrated that the provision of public goods is more efficiently provided by the government, the relative efficiency of government versus markets in practice is questionable. In recent years, there has been an increasing trend toward contracting out to the private sector and public-private partnerships. The reasoning behind this evolution rests with the assumption that the ownership of a public good should lie with the party that values its benefits more.

ACKNOWLEDGMENT

The author would like to thank Dr. Steven A. Peterson, Pennsylvania State Harrisburg and Gabi Huber, Clemson University, for suggestions to an earlier draft.

^h\$168 billion was donated by the public to charitable organizations in 1999 (Ref.^[5]).

ⁱMarket failures arise when the decentralized production of goods yield Pareto-inefficient outcomes. Pareto efficiency rests on the assumption that the free markets are able to yield an optimal distribution of goods in society. This means that it is impossible to find another allocation that makes someone better off without making anyone worse off (Ref.^[1]).

Public Policy

Steven A. Peterson

Middletown, Pennsylvania, U.S.A.*

INTRODUCTION

Public policy is normally conceived as government action to address some problem. The central focus is, as the old phrase has it, who gets what when how. Policy is the end result of a complex decision-making system, encompassing many actors. This article explores standard definitions, a typology of policy types, and some debate over how well one can draw a boundary between “public” policy and “private” policy.

DEFINITION

Public policy, in its most simple definition, is that which government does. James Anderson puts it more formally:^[1] “A relatively stable, purposive course of action followed by an actor or set of actors in dealing with a problem or matter of concern.” Another standard view is by Peters:^[2] “public policy is the sum of government activities, whether acting directly or through agents, as it has an influence on the lives of citizens.”

POLICY TYPES

Over time, numerous policy experts have suggested that there are different types of policies, and that the political struggle over public policy depends on the type of policy at issue.^[3,4] One illustrative example is a typology created by James Q. Wilson.^[5] Table 1 indicates the two factors that define the typology—the extent to which benefits are concentrated or distributed, and the extent to which costs are concentrated or distributed among groups. The combination of costs and benefits, according to Wilson, helps to shape political discourse.

Majoritarian politics involves policy issues that have distributed (widespread) benefits and distributed costs. That is, many individuals and groups will pay for the policy to be implemented and services delivered, and many will benefit. This type of policy issue is visible and depends on development of a winning majority coalition in support of a policy choice. If a

widespread coalition determines that the issue calls for government involvement, then the policy is apt to be approved. This type of policy engenders societywide discussion and debate. A classic example would be social security, in which a vast number of citizens pay into the fund and from which large numbers of citizens at retirement will be able to receive payments.

Entrepreneurial politics is the result of a policy entrepreneur (or policy entrepreneurs) rallying support to a cause on behalf of a significant segment of the public and overcoming the opposition of a relatively small interest. In this case, costs are concentrated to a relatively small segment of society and benefits are widely distributed. An example would be Ralph Nader serving as a policy entrepreneur with respect to auto safety. The automobile industry had to invest in greater safety, to the benefit of the larger public.

Client politics occurs when a narrow interest group lobbies government successfully for some benefit without arousing mass opposition; the many pay for the benefit of the few. That is, society at large may pay for the benefits accruing to a few, as the recent farm bill, with subsidies to agricultural sectors coming out of general tax revenues, illustrates. A small sector—agricultural business—benefits, while the public pays for these benefits through taxes.

Interest group politics is a contest between two narrowly defined groups. This type of policy conflict is often invisible to the larger public because the contest is between two relatively narrowly defined groups. One group wins and another loses. An example might be National Labor Relations Board decisions, when one side will win and one will lose, with the debate taking place largely out of public scrutiny.

THE BLURRED BOUNDARIES BETWEEN PUBLIC AND PRIVATE POLICY

Public policy, for some analysts, is more broadly defined than the textbook definitions at the outset of this entry. Some have argued that public policy speaks to decisions made by powerful actors that affect the lives of many people. These decisions have to be intentional and they must bind those people affected by the decisions; that is, once the decision is made, affected

Table 1 James Q. Wilson's matrix: interest groups and policy types

Perceived benefits	Perceived costs	
	Distributed	Concentrated
Distributed	Majoritarian politics	Entrepreneurial politics
Concentrated	Client politics	Interest group politics

people must go along or suffer consequences. By this definition, decisions made by large and powerful corporations are as much public policy as decisions made by the United States, the state of New York, or the city of Chicago.^[6,7]

Normally, those who study public policy restrict the definition to decisions made by government, but the distinction between private and public sectors is untenable, according to critics. More important, it shields from inquiry decisions made by non-government organizations that are as much public policy as anything that government does. In this manner, such organizations are not responsible or accountable to the people. In a democracy, the people are supposedly the ultimate repository of authority over public policy.

By refusing to see that, for instance, corporations make policy as much as government does, society allows them to continue to operate outside democratic norms, which would call for public policy makers to be responsible and accountable to the people. If businesses make public policy, then—according to the democratic rules of the game—they ought to be directly responsible and accountable to the people as well.

First of all, though, how can it be said that non-governmental actors actually make policy? Some definitions of policy may not specifically mention government, but do emphasize the idea of decisions being made that affect substantial numbers of people.^[8] Once stated in this manner, according to critics, it becomes clear that non-government actors can make policy.

Mark Nadel argued that corporations often make decisions that are intentional, binding, and affecting large numbers of people with respect to some tangible or symbolic allocation of goods or services.^[6,9] United States Steel was once one of the giant American corporations. One of its landmark factories was in Gary, Indiana. Its furnaces belched smoke into the air, affecting the quality of life, health, and property of those living downwind. The company did not address issues of cleaning up its emissions. Thus, it made an intentional decision, binding the people of Gary to that decision and affecting many people with considerable consequences in the process.^[10] That this is public policy,

just as a change in income tax structure or promulgation of some regulation, seems obvious to critics like Nadel. Nadel also noted the decision by the major auto companies in the mid-1950s not to research antipollution technology.^[9] This is as much environmental policy as the Clean Air Act.

Private sector public policy is hidden from normal political discourse. People so commonly define public policy in terms of government actions that what we think of as “private” policy remains hidden. The costs of this are substantial. Factories shut down operations in a community, often devastating a local economy. The decision is considered “private,” even though its consequences are no different from a military base shutting down or a government program ceasing to spend money on a project in a district. People's lives are uprooted; local government's ability to pay for services is seriously compromised because such companies are normally important contributors to the local tax base.

CONCLUSION

This suggests that students of public policy might want to consider more generally the contours of the subject matter. Although the standard conceptualization of public policy as a government decision makes much sense, considering the implications of the expanded definition, along the lines suggested by Dahl and Nadel, might well further enrich understanding of the subject matter.

Public Policy Formation Under Conditions of Ambiguity

Nikolaos Zahariadis

Department of Government, University of Alabama at Birmingham,
Birmingham, Alabama, U.S.A.

INTRODUCTION

Multiple Streams (MS) is a framework, approach, or lens—I use the terms interchangeably—that can be used to understand (predict and explain) the policy process under conditions of ambiguity. Although it could conceivably be extended to cover the entire process of policy making, it has been developed and applied only as an aid to understanding policy formation (agenda setting and decision making). Drawing inspiration from work on bounded rationality and organization theory as formulated by theorists such as James March, John Kingdon, Herbert Simon, and others, the framework assumes conditions of ambiguity and a temporal sorting order. *The main argument is that policies are the result of problems, solutions, and politics coupled, or joined together, by policy entrepreneurs during open windows of opportunity.*

ASSUMPTIONS AND BASIC LOGIC OF THE FRAMEWORK

MS theorizes at the systemic level, and it incorporates the entire system or a separate decision as the units of analysis. Much like systems theory, it views choice as collective output formulated by the push and pull of several factors. It shares common ground with chaos theories in being attentive to complexity, in assuming a considerable amount of residual randomness, and in viewing systems as constantly evolving and not necessarily settling into equilibria.^[1] Collective choices are not merely the derivatives of individuals but rather the combined result of structural forces and internal processes that are highly context dependent.^[2]

Ambiguity

Ambiguity refers to “a state of having many ways of thinking about the same circumstances or phenomena.”^[3] These ways may not be reconcilable, creating vagueness, confusion, and stress. It is different from uncertainty, a related concept, in that the latter refers to the inability to accurately predict an event.

Ambiguity may be thought of as ambivalence, whereas uncertainty may be referred to as ignorance or imprecision.^[4] While more information may (or not) reduce uncertainty,^[5] more information does not reduce ambiguity. For example, more information can tell us how AIDS is spread, but it still will not tell us whether AIDS is a health, educational, political, or moral issue. MS is a lens that deals with policy making under conditions of ambiguity. It does not explain why politicians sometimes pursue ambiguity but how policies are made when ambiguity is present.

At the heart of the lens lies a garbage can model of choice. In an insightful article, Cohen, March, and Olsen^[6] outline such a model that explains decision making in organizations—or decision situations—they term “organized anarchies” where ambiguity is rampant. These organizations, such as universities or national governments, are characterized by three general properties: fluid participation, problematic preferences, and unclear technology.

First, participation in such organizations is fluid. Turnover is high, and participants drift from one decision to the next. Legislators come and go, and bureaucrats, especially high-level civil servants, often move from public service to private practice.

Second, it is generally observed that people frequently do not have a clear, well-articulated set of preferences. To say that policy makers almost never make their objectives crystal clear is hardly novel, but it is true that quite often, time constraints force politicians to make decisions without having formulated precise preferences. Decisions are made and may even be facilitated by opaqueness. In contrast to most business firms in which the ultimate goal is clear—namely, to make a profit—organized anarchies operate on the basis of multiple and diverse objectives.

Third, technology, that is, an organization’s processes that turn inputs into products, is unclear. Members of an organized anarchy may be well aware of their individual responsibilities, but they exhibit only rudimentary knowledge concerning the way their job fits into the overall mission of the organization. Jurisdictional boundaries are unclear, and turf battles between different ministries are a common occurrence.

Temporal Sorting

Under such extreme conditions, theories based on rational behavior are of limited utility. Because problems and preferences are not well known, selecting the alternative that yields the most net benefits becomes an impossible task. Problems are difficult to define precisely. The problem under conditions of ambiguity is that we do not know what the problem is. Its definition is vague and shifting. In contrast to models that stress consequential action, the logic of multiple streams is based on temporal order. Choice has more to do with the simultaneous evocation of problems and solutions rather than with any inherent correlation between them. Time is a unique, scarce resource. Because the primary concern of decision makers (policy makers, business executives, or top civil servants) is to manage time effectively rather than to manage tasks,^[7,8] it is reasonable to pursue a lens that accords significance to time rather than rationality. This translates into a process in which individuals are viewed as less capable of choosing the issues they would like to solve and more concerned with addressing the multitude of problems that are thrust upon them largely by factors beyond their control.

Assumptions

Three assumptions guide the framework:

1. *Individual attention or processing is serial; systemic attention or processing is parallel.* On the one hand, because of biological and cognitive limitations, individuals can only attend to one issue at a time. On the other hand, division of labor in organizations or governments enables them to attend to many issues simultaneously. This capacity is, of course, not infinite, but it is reasonable to assume that government can put out fires in Colorado, conduct trade negotiations with Greece, and investigate mail fraud at the same time.
2. *Policy makers operate under significant time constraints.* Obviously, these people do not have the luxury of taking their time to make a decision. While this does not imply that all decisions are crises, it suggests that there is a sense of urgency in addressing them. In effect, such time constraints limit the range and number of alternatives to which attention is paid.
3. *The streams flowing through the system are independent.* This assumption is related to the first one in that if systems can do things in parallel, then each element or stream may be conceived as having a life of its own. The

framework postulates three separate streams flowing through a system: problems, solutions (policies), and politics. Problems are concerns that individuals inside and outside the organization have. They involve, but are not limited to, such issues as profitability, work satisfaction, career advancement, and promotion. Solutions are people's products; they are answers to questions that may not be generated only when needed. Thus, each stream seems to obey its own rules and flows largely independently of the others.

THE STRUCTURE OF THE THREE STREAMS

The basic formulation was first put forth by Kingdon,^[9] who used the multiple streams framework to illuminate two predecision processes in the United States: agenda setting and alternative specification. His work has been subsequently revised to examine the entire policy formation process (agenda setting and decision making) in a comparative context and in domestic as well as foreign policy. I proceed by examining the structure of each stream separately, and then I assess the effects of coupling in aiding our understanding of policy formation.

The condensed version of the argument is as follows: *There are three independent streams flowing through every policy-making system. There is a problem stream that includes indicators or crisis events that come to be defined as problems by policy makers. The second stream is the policy, or solution, stream, which comprises ideas generated in narrow policy networks. The third is the political stream that contains the administration, Congressional leaders, etc. The chances that any one idea will be adopted increase dramatically when skillful policy entrepreneurs couple or join together the three streams during open policy windows, defined as changes in the problem or political streams. So, the key to understanding how policies are made under conditions of ambiguity is to elucidate the dynamics of each stream and to specify the circumstances under which coupling is more likely to occur.*

The problem stream consists of various conditions that policy makers and citizens want addressed. Examples are government budget deficits, environmental disasters, inflation, rising medical costs, and so on. The means that policy makers use to find out about these conditions include indicators, focusing events, and feedback. Indicators show the magnitude of a condition as well as the scope of change. An example of a problem is high government borrowing needs.^[10,11] The British Conservatives used the Public Sector Borrowing Requirement to identify those needs. The fact

that it rose to historically high levels by the early 1980s provided impetus to do something about it. The same could be argued about the French. Their borrowing needs were judged to be at historically high levels. But, they were lower than those of Britain. The point that needs to be stressed is that each government looked at the historical record and not to other countries to make this judgement, although cross-national comparisons are often made.^[9] Focusing events also draw attention to problematic conditions. Examples of focusing events include prolonged strikes and train or airplane accidents. Feedback from previous programs is important in that it helps highlight what works and what may not. Successfully implementing a solution in one area may spill over to another, facilitating the adoption of the same solution in a seemingly unrelated area. The case of spillover of privatization from the area of oil to telecommunications in Britain is a good example.^[11]

The politics stream includes a number of political parties or coalitions competing for a chance to govern and thus directly affect the policy process. They are the policy makers who will ultimately make the decisions whether to adopt or not to adopt a specific proposal. Collectively, parties carry an ideological bend that makes them more receptive to certain ideas. Conservatives generally have a proclivity toward more market-oriented policies and socialists/leftists do not, with several exceptions, of course. There are at least two elements in the political stream: national mood and party ideology. Kingdon^[9] advocates keeping them separate, although Zahariadis^[11] proposes they be combined because of significant problems operationalizing the national mood.

The policy stream includes a “soup” of ideas that compete to win acceptance in policy networks. Two criteria affect the availability of proposals in the policy stream: value acceptability and technical feasibility. They are important in securing the chances that any one option will receive attention past the subsystemic level. Ideas that do not conform to the values of many specialists in a policy network and which are more difficult to implement stand a lesser chance of receiving attention by national policy makers.

Not all policy networks are created equal. In the original conception of multiple streams, ideas are recombined and rise to the top only incrementally.^[9] But this need not be the case. An examination of the rise (or not) of privatization in British and German policy networks revealed systematic differences depending on the structure of the networks.^[12] Institutional configurations, or to put it differently, the level of integration, differ across countries, affecting the mode and tempo of ideas, that is, how ideas germinate in the policy stream and how fast they rise to prominence. Integration refers to linkages among participants and is

distinguished by variations in four dimensions: size, mode, capacity, and access. Based on these dimensions, networks can be classified as more or less integrated. Less-integrated networks are larger in size, have a competitive mode, lower administrative capacity, and less restricted access. Conversely, more integrated networks are smaller in size, have a consensual mode, higher capacity, and more restricted access. Less integrated networks are likely to encourage a movement of solutions from conception to prominence through quantum to gradualist evolution, whereas alternatives in more integrated networks are more likely to follow an emergent to convergent evolution.

Policy entrepreneurs are individuals or corporate actors who attempt to couple the three streams. They are more than mere advocates of particular solutions; they are power brokers and manipulators of problematic preferences and unclear technology. Of course, not all entrepreneurs will be successful at all times. The more successful ones are those who have greater access to policy makers. For example, the Adam Smith Institute had greater access to the government during Thatcher's tenure in power in the United Kingdom, because their ideologies matched more closely than those of other groups. Hence, options put forth by individuals associated with the Institute had a greater chance of falling on receptive ears in government.^[13] Second, entrepreneurs with more resources, i.e., the ability to spend more time, money, and energy, to push their proposals, have greater rates of success.

So far, the analysis has focused on entrepreneurial characteristics. Entrepreneurs must also employ strategies to accomplish their goal of coupling the three streams. The following list of strategies is not exhaustive, but it gives a good idea of how entrepreneurs pursue coupling and what factors influence their success: framing, salami tactics, and the strategic use of symbols.^[14] All aim to manipulate the various dimensions of policy images to activate values within with the explicit aim of gaining a receptive audience among policy makers. These strategies are employed largely at the systemic or national level. Framing involves the manipulation of dimensions to represent solutions to specific problems as gains or losses. Entrepreneurs seek to capitalize from people's tendency to hate to lose more than they like to win. If solutions espoused by entrepreneurs are large deviations from the status quo, successful coupling is more likely when problems are represented as losses; if options represent smaller deviations or a preservation of the status quo, coupling success is more likely when problems are framed as gains. A salami tactic is the strategic manipulation of sequential decision making. Entrepreneurs are assumed to have a grand design of the desired outcome. However, because they are reasonably certain

their desired solution will not be adopted because it is too risky, they slice the process into distinct stages. Doing so encourages agreement in steps. By the time policy makers become aware they are being manipulated, they have invested too much to depart from the course of action. Entrepreneurs who are placed at a high level in government, operate under crisis conditions, and pursue salami tactics are more likely to be successful at coupling. Finally, symbols bias choice through emotion and cognitive meaning. They allow entrepreneurs to link the macro to the micro by using the same symbol to appeal to many individuals. Some symbols have predictable effects on individuals in terms of affect and meaning, particularly those commonly termed as higher-order symbols. Higher-order symbols, such as the national anthem or the flag, are relevant to the community at large and possess two characteristics. They are capable of arousing more intense emotions than others and are closer or more relevant to an individual's identity. Entrepreneurs who use higher-order symbols have a greater chance of finding a receptive political audience.

Success in coupling also depends on other factors. Coupling is more likely to be successful during open policy windows. Windows are ephemeral opportunities created by changes in the problem and politics streams. They provide the context within which coupling takes place. The mechanisms that link opportunity to choice are three: urgency, fear, and crisis-mandate. The argument put forth by Kingdon^[9] was that neither problems nor solutions drove the policy process, although he emphasizes the point that solutions frequently search for problems rather than the other way around. But, the argument can be refined by specifying the conditions under which a policy is in search of a rationale.^[13] When windows open in the problem stream, coupling is more likely to be consequential, that is, finding a solution to a given problem. When windows open in the politics stream, coupling is more likely to be doctrinal, that is, finding a problem to a given solution.

SPECIFIC ISSUES AND CONCERNS

The lens can be extended to cover the entire process of policy formation, enable the comparative study of public policy, accommodate a considerable degree of complexity, model a process that is fluid and dynamic, and impose some degree of order and structure while acknowledging the importance of serendipity. The critics, however, point to several drawbacks. I will reflect upon three questions that have been raised: 1) are the streams really independent?; 2) are open policy windows always ephemeral?; and 3) what is the impact of deadlines?

Are the Streams Really Independent?

In a penetrating critique, Gary Mucciaroni^[15] questions the appropriateness of conceptualizing independent streams. The streams can be more fruitfully viewed as interdependent, he maintains, and changes in one stream can trigger or reinforce changes in another, making coupling much less fortuitous and the process more purposive and strategic. For example, the problem of U.S. tax reform was tied to the supply-side tax cuts proposed by conservatives in symbolic and substantive ways long before Reagan's advent to power opened a policy window. Weir^[16] echoed a similar point. Sabatier and Jenkins-Smith's^[17] advocacy coalition framework is partly an attempt to view the politics and policy streams as tightly linked. In other words, coupling, Mucciaroni^[15] concluded, takes place even in the absence of a policy window. Kingdon^[9] opened the possibility that coupling may take place in the absence of an open window, but he was careful to point out that this must be determined empirically.

Problems, policies, and politics are independent of one another in several ways. Politics operate on the systemic level of analysis, policies are developed on a sectoral or subsystemic level, and problems may be developed on a systemic or a sectoral level. Because the framework views choice from the system's point of view, it is possible to conceptualize several things happening simultaneously and independently of one another (first assumption). The policy and political streams are independent, because they involve mostly different people with different preoccupations and orientations.^[9] Specialists in policy communities include experts who share an interest in one narrow area, e.g., telecommunications, health, education, etc., and who concentrate on honing proposals relevant to the area, attend to technical details, conduct cost-benefit analyses, and the like. The political stream involves a wider array of people, most of whom have nothing to do with this narrow area. It includes the entire government, for example, agriculture, finance, or transport ministers, party activists, or religious authorities. They are preoccupied with elections, public opinion, or military operations, which are preoccupations quite distinct from, say, health issues. Solutions are developed in narrow communities and not in broad political discourse, where grandstanding and simplicity rather than technical detail are the key ingredients.

The problem stream differs from the policy stream in that solutions are developed separately from problems. This does not mean that solutions are not developed to solve problems, it simply means that the same solution may be attached to different problems at different times. The example of academic discourse illustrates this distinction well. The garbage can model was conceived as a solution to the problem of

organizational decision making under ambiguity. Kingdon^[9] adapted the same solution to the problem of agenda setting in the U.S. federal government. Another analyst may further adapt the same solution to describe the implementation process of UN decisions. Problems change, while the solution remains the same. Feldman^[3] provided a multitude of examples whereby bureaucratic analysts drafted reports and estimates before any problems arose on the rationale that developing them would take much longer than the time available if they waited to draft the reports after a request was made. Such practice leads to the development of inventories of solutions to address new problems.

Are Open Policy Windows Always Ephemeral?

A policy window is a temporal stimulus for choice. Windows not only signal the temporal limits of the coupling process to policy entrepreneurs, but they also help structure the search for appropriate problems or policies that may be palatable to the policy makers of the day.

Windows may sometimes not be temporary. Sharp^[18] suggests that certain characteristics make an issue continuously activated, i.e., it is always on the agenda, but she does not elaborate on the implications for MS. An issue such as drugs and drug policy has dramatic potential, high visibility, a plethora of organized interests that constantly offer expert diagnoses and prescriptions, and a multitude of consequences—social, personal, political, economic, or physiological—which make it a favorite supplement to a variety of other issues. If certain windows are not fleeting, what are the effects on coupling over time? Do they lead to greater partisan conflict, more symbolic action, or more problem solving?

What is the Impact of Deadlines?

The main way that decisions are made in MS is by entrepreneurial skill. This implies that there are no set deadlines on when decisions need to be made. Weiner^[19] points out that deadlines have a significant impact on the way the lens works. They erect a barrier around the choice that resists the entrance of new problems or the activation of new participants. This causes a dramatic increase in the amount of energy and attention that active participants must exert to make the choice, because they have to withdraw from other choices to stay on top of their obligations to meet the deadline or they must withdraw from making the choice before them. When a deadline is set, policy makers compare the amount of energy it would require to solve or address all problems they have set to solve

and the energy required to make this particular decision. Thus, if they decide they have accepted more problems than they can handle under the new time constraints, they will likely reject some problems and allow them to be addressed in other parts of the system.

Decision cycles are equally important factors to consider, as they close off the process and reduce political stress and instability. The lens paints a fluid picture of an open-ended policy-making process. While a multitude of solutions and problems are dumped into the garbage can, the process has a limit. Cycles of opportunities limit the focusing frames around which groups coalesce, reduce the escalation of demands by winners and losers, and meld differences among competing groups.^[20] Clearly defined cycles, such as the annual passage of the budget, provide a signal as to the duration of the window. To an extent, they regulate conflict by providing multiple opportunities to air out demands. This, in turn, limits options for dissent, because dissent can be spread over several years, and because not every problem can be aired at that point. Past practice suggests which problems and solutions or their relatives may be appropriately debated. The intensity of conflict is also suppressed, because defeat at one point is not necessarily the end but rather the beginning of a new effort to “get your way next time.” Similarly, success is merely temporary and not overwhelming, because another budget and, consequently, another compromise will have to be made next year. Such repetition also leads to a better understanding of what opponents want, which tends to reduce differences among frames held by individuals and to aggregate them into broad coalitions. For example, the annual debate over salaries or other benefits helps distribute information about various grievances. Individual members learn more about how other individuals feel about the same issue and are better capable of coalescing around common themes. From an individual member’s point of view, cycles eventually promote the creation of coalitions, because there is greater likelihood for success in numbers. From the system’s point of view, cycles reduce diversity and conflict to a more manageable level. In short, cycles are hypothesized as promoting order and coordination in otherwise disorderly organized anarchies.

MULTIPLE STREAMS AND THE STAGES HEURISTIC

By virtue of focusing attention on the entire policy formation process (agenda setting and decision making), multiple streams enable research to move beyond the stages heuristic, which is the dominant framework for understanding the policy process. It provides a better

theory of the policy process by facilitating cumulation of knowledge and integration of models across various stages that have been previously examined separately and in isolation. The end result is the ability to explain more with less.

Early in the development of policy studies as a field of inquiry, Lasswell^[21] proposed a conceptual map that would enable analysts to maintain a general image of the process of collective choice, while cutting the process down to analytically manageable proportions. The list of stages he proposed, which was subsequently refined by others, is important not simply for practical reasons, but primarily for theoretical ones. Each stage, such as initiation, implementation, evaluation, and so on, has a distinctive characteristic that gives it “a life and presence of its own.”^[22] It is argued that the actors involved in each stage are different as well as the purpose and dynamics of activities, making the distinction between stages an analytically useful enterprise.^[23]

While the stages heuristic has served analysts well by stimulating considerable research, it has been criticized recently as conceptually inadequate and stifling rather than facilitating theory development. Nakamura^[24] views the issue as one of boundary specification. Are the boundaries between the stages as precisely defined as their proponents suggest, and if not, is this not evidence that the distinctiveness is artificially created? Sabatier^[25,26] and Sabatier and Jenkins-Smith^[17] go further. Apart from questioning the assumption that there is one rather than many interacting cycles, they argue that the stages heuristic is not a causal theory but a taxonomy, which can be misleading, because research in each stage proceeds without reference to work in other stages. Moreover, they maintain that the description of stages is often inaccurate. Each stage is affected by others. For example, agenda setting is affected by evaluation of existing programs; implementation difficulties influence the likelihood of adopting specific legislation. Unfortunately, it appears “the map” initially created to bring a broad overview of the process without sacrificing analytical manageability has strayed off its original intention. Models and theories are proposed and tested for each stage in isolation of other stages, fostering disjointed theory development. As a result, the broad general picture of the process is lost in a sea of stage models which, while acknowledging their interconnectedness, nevertheless discourage any effort to link them in a theoretically meaningful way.

Multiple streams offer a way to overcome the limitations of the stage heuristic. While it does not cover the entire policy process, although it conceivably could, it provides a way to understand the policy-making process of two stages with one model of reference. First, it does not draw boundaries between stages. The benefit from such “non-distinction” is the ability to develop

concepts and processes that are internally consistent and meaningful across stages. It promotes rather than impedes theoretical links between stages. Second, it provides a better, clearer view of the larger process. Third, it elaborates on causal mechanisms that give rise to theoretical coherence and hypothesis testing. Fourth, multiple streams is a better alternative to the stage heuristic in that it helps explain a greater portion of the policy process by reference to the same factors. If one accepts the argument put forth by Lakatos^[27] that cumulation of knowledge is the basic aim of science and that parsimony is of great value, then the ability to use the same set of factors to explain phenomena that used to demand two or more models gives multiple streams a qualitative edge. Although many conceptual refinements have yet to be made, relative to the stage heuristic, multiple streams is a better theory.

CONCLUSION

Multiple streams is a lens that examines the process of making policies under conditions of ambiguity. According to multiple streams (MS), policies are the result of actions by policy entrepreneurs who couple three streams—problems, policies, and politics—during open windows of opportunity. In this concluding section, I chart a course for future research.

Does policy affect politics? Are there issue properties that alter the policy process in predictable ways?^[15,28] Rommetveit^[29] suggests that prime candidates for garbage cans are those decision processes that take place under changes in normative structures (basic value-priorities in a polity) and when no active participant dominates the policy process. When a society is in the process of reordering its values, established norms that underlie state–society relations are challenged. As a result, the role of experts and the wisdom of bureaucrats is questioned, and dissenting groups might use this opportunity to pursue their diverging claims. The possible activation of new groups and the wide disagreement as to the relevant values upon which to base the decision will, in turn, increase ambiguity and permit the evocation or appearance of new problems and solutions. Such desegmentation of previously established links between windows, problems, and politics complicates the process as new and perhaps unrelated elements are dumped into the can. In this light, the issues of privatization or government reform are good candidates for applying MS.^[30,31]

MS has been investigated so far as if decisions are discrete and unrelated to one another. Policy making, however, involves sequences of decisions that are linked together through the important process of feedback. Kingdon^[9] noted that feedback plays a pivotal

role in helping policy makers define or redefine problems. Feedback, however, may operate in all three streams as well as in coupling. Experts in policy communities formulate solutions partly on the basis of previous experience with similar problems. Entrepreneurs keep inventories of coupling techniques and experience. Precedent makes it easier to transplant issues or success from one area to the next. There is a lot of learning going on in public policy, and feedback plays an important role in fostering it. Exploring further into the mechanisms that facilitate this process might yield insights into entrepreneurial strategy and sense of timing. What effect does sequential coupling have on the lens? How do entrepreneurs come to recognize opportunities, and what influences their timing strategies? When are old decisions likely to be reexamined?

How should policy makers cope with an ambiguous world? What lessons does MS have to offer to democratic governance? Although reasonable and obvious, these questions have not really been explored. In order for democracy to work properly, there needs to be a strong sense of accountability and efficacy. Policy makers are supposed to make decisions that conform to the wishes of at least the majority of the citizenry, but they must also solve as many problems confronting the polity as possible. In an earlier study of leadership in universities, a situation slightly different from democracies in that university presidents are hired and not elected, Cohen and March^[32] suggested *inter alia* persistence and overloading the system by making many proposals on the rationale that some will pass. Looking specifically at bureaucratic hierarchies, Padgett^[33] concluded that managers had better follow a “hands off” approach, provided they tend to personnel policies and structural design. For example, presidents should not fight subunit conflict but rather reorganize high- and low-saliency issues into relevant divisions and then hire activist and conservative secretaries (or vice presidents) to deal with the respective divisions. High saliency issues tend to flow upward in the hierarchy, and they are precisely those issues in which upper management attempts to be involved. It is best to hire someone who seeks that involvement. Low saliency issues tend to be addressed at a lower level and require a conservative manager who is not obtrusive. Crecine^[34] added to this strategy the manipulation of windows, which in effect alters the context. The lens assumes windows are opened by changes in the political or problem streams.^[9] Some windows are subject to manipulation, particularly those associated with budgets or public procurement efforts. The same can be said of elections. They can be called in parliamentary democracies at the prime minister’s discretion. For example, Margaret Thatcher’s 1983 decision to hold legislative elections a year ahead of schedule caught the opposition divided and

busy with the fallout from the Falkland War. Her subsequent victory enabled her to pass the politically costly and complex bill authorizing the sale of British Telecom with relative ease.^[10]

Democracies differ in that policy makers flow in and out of the system as one is elected (or reelected) to the post and the others are not. What are the implications for governance? March and Olsen^[35] sketched some ideas, but they did not model them. Zahariadis^[14] suggested that the policy process is replete with manipulation of facts and people, but he did not draw implications for democratic governance. While the multiple streams framework has not yet provided answers to these important questions, it is a good starting point for investigating policy making under conditions of ambiguity.

Public Procurement

Robert E. Lloyd

U.S. Department of State, Ft. Lauderdale, Florida, U.S.A.

INTRODUCTION

When private individuals or corporations buy things, they may use the terms “purchasing” or “buying” to describe their actions. In government organizations, many different terms and definitions are used when referring to the buying function, from “public procurement” to “contracting” or “acquisition” and many other variations. The wide variety of terms and definitional ambiguities permeate the practice and profession. Despite the fact that public procurement has a centuries-old history, clarity in what practitioners and scholars mean when they refer to “public procurement” is sometimes lacking. Nevertheless, there are common themes, roles, and responsibilities that span the wide range of governmental organizations involved in procurement.

LEGAL DEFINITIONS

Definition of the Federal Government

In 1984, the US Government converted to a new system of regulations governing how federal agencies buy things. The former Federal Procurement Regulations published by the General Services Administration (GSA) and the Defense Acquisition Regulation (known as the Armed Services Procurement Regulation until 1976) issued by the Department of Defense, along with the National Aeronautics and Space Administration Procurement Regulation were combined into a new set of rules called the Federal Acquisition Regulation (FAR; Title 48, Code of Federal Regulations, Chap. 1). There was a deliberate attempt to replace the term “procurement” with “acquisition,” in part to distinguish the new rules from the old, as noted in the following excerpt from the FAR (Section 2.101, Definitions):

“Acquisition” means the acquiring by contract with appropriated funds of supplies or services (including construction) by and for the use of the Federal Government through purchase or lease, whether the supplies or services are already in existence or must be created, developed, demonstrated, and evaluated. Acquisition begins at the point when agency needs

are established and includes the description of requirements to satisfy agency needs, solicitation and selection of sources, award of contracts, contract financing, contract performance, contract administration, and those technical and management functions directly related to the process of fulfilling agency needs by contract.

“Procurement (see “acquisition”).”

Although the terms “procurement” and “contracting” have generally fallen into disfavor at the federal level, they still persist in several forms. For example, the federal office responsible for Government-wide policy in the Office of Management and Budget is known as the Office of Federal Procurement Policy, and the job series for buyers is referred to as “contracting.” At the federal level, Congress passed a new legislation (the “Services Acquisition Reform Act” or Defense Authorization Act for 2004, Public Law 108-136, title XIV, Section 1411) that defines in detail what “acquisition” means:

“The term “acquisition”—

- A. means the process of acquiring, with appropriated funds, by contract for purchase or lease, property or services (including construction) that support the missions and goals of an executive agency, from the point at which the requirements of the executive agency are established in consultation with the chief acquisition officer of the executive agency; and
- B. includes—
 - i. the process of acquiring property or services that are already in existence, or that must be created, developed, demonstrated, and evaluated;
 - ii. the description of requirements to satisfy agency needs;
 - iii. solicitation and selection of sources;
 - iv. award of contracts;
 - v. contract performance;
 - vi. contract financing;
 - vii. management and measurement of contract performance through final delivery and payment; and

- viii. technical and management functions directly related to the process of fulfilling agency requirements by contract.”

Although the new definition is similar to that appearing in the FAR, by promulgating this new, more expansive definition, Congress signaled its intent to view the buying process in a broader perspective.

In addition, federal legislation also distinguishes a “procurement contract” from a grant or cooperative agreement. A contract is to be used when “the principal purpose of the instrument is to acquire (by purchase, lease, or barter) property or services for the direct benefit or use of the United States Government” (31 U.S.C. 6303). Grants and cooperative agreements, on the other hand, involve a transfer of funds to a source outside the federal government for a public purpose, such as research.

Definitions of the State and Local Government

The American Bar Association’s Model Procurement Code^[1] defines “procurement” as “buying, purchasing, renting, leasing, or otherwise acquiring any supply, service, or construction, including description of requirements, selection and solicitation of sources, preparation and award of contract, and all phases of contract administration.” Many jurisdictions have adopted all or part of this model for their public procurement rules. For example, the State of Arizona’s Revised Statutes (Article 1, Section 41-2503, paragraph 15), made effective in 1985, adopt this definition for public procurement by the state.

GOALS AND PROCEDURES

Public procurement is often most visible owing to the strict procedures it follows. At all levels of government, the emphasis is on transparency, enabling the public to learn of contracting opportunities, and facilitating competitive private sector responses. The three primary goals of public procurement are fairness, efficiency, and promotion of socioeconomic objectives. Public procurement is held to a higher standard than private sector buying in that governments are expected or required to publish advance notices of upcoming contracts. Fairness demands that the public be allowed to participate, and Congress passed the Competition in Contracting Act of 1984 to mandate “full and open competition” or allowing all responsible sources to compete for contracts awarded by federal agencies.

Efficiency is likewise a goal of public procurement, as revenue from income taxes is being spent and must be safeguarded from waste. Many efficiencies have been introduced in public procurement in recent years, including the acquisition of commercial items rather than items meeting government-unique specifications, expanded use of simplified acquisition techniques and electronic commerce tools such as posting solicitations for upcoming contracts on internet web sites, and the implementation of purchase cards to simplify transactions of small value. For example, the federal purchase card program allows qualified cardholders to buy using a bank-issued card up to the “micropurchase” limit of \$2500 per transaction.

As a result of the large amount spent in public procurement (over \$200 billion per year at the US federal level, and State and local government procurement exceeds even that amount in the aggregate), many see public procurement’s role as a means of implementing socioeconomic policy.^[2] Public procurement is often used as a means of leveraging this significant purchasing power. In addition to the goals of fairness and efficiency, the added aims of assisting small businesses (as described in considerable detail in FAR Part 19), promoting the buying of environmentally friendly products, implementing wage increases and fringe benefit packages, as in the “living wage” ordinances found in local government procurement,^[3] and similar programs comprise an important aspect of public procurement.

The operating procedures followed in public procurement generally fall into three phases:

- i. *Planning, publicizing, and soliciting:* During this stage, the public procurement office works with its clients to develop a complete description of the government’s needs. The procurement office then publishes some form of public notice regarding the upcoming contract (on an internet web site such as www.fedbizopps.gov, by newspaper advertisement, etc.). A written solicitation document is then published describing the government’s needs and asking for responses from the private sector. The most common types of competitive solicitations are the Request for Proposals (RFP) and the Invitation for Bids (IFBs). RFPs (negotiated procurement, which allows negotiation with those submitting proposals) are typically used for more complex efforts, and IFBs (which involve a public bid opening and no negotiation) are normally limited to contracts for routine supplies or construction. Federal agencies generally use RFPs and rarely use IFBs, while the situation is sometimes the reverse in local government procurement. The most important functions of the solicitation are to define the government’s

needs, explain how to submit an offer, outline how the government will evaluate the responses and pick the winning firm, and include the clauses, terms, and conditions that will become part of the contract.

- ii. *Evaluation and award:* Once the proposals or bids have been received, they must be fairly evaluated by the procurement office and its customers. A contract may be awarded based on the initial response from the offering firms, or in the case of a negotiated procurement, the government may choose to conduct negotiations with one or more of the highest rated firms. This phase of public procurement is also known as source selection, and its intent is to choose the most advantageous contractor after following the procedures stated in the solicitation. For negotiated procurement, the procurement office typically adheres to an evaluation plan that describes how the proposals will be evaluated to ensure impartiality in the process. Ethical issues are addressed during this phase as well, such as avoiding conflicts of interest by requiring proposal evaluators to certify that they do not own stock in any of the competing companies. At the conclusion of the evaluation, someone with delegated contracting authority will sign the contract with the successful firm. During this process, disappointed firms may have an opportunity to file a protest if they believe they were unfairly treated.
- iii. *Contract administration:* After the contract is signed, the procurement office must administer it. That means monitoring the work performed by the contractor, including the important functions of receipt, inspection, and acceptance prior to payment. Warranties must be administered, such as when computer equipment is purchased, or for construction contracts that often include a one-year warranty for the work and extended warranties for equipment. Public procurement may involve resolving contract disputes arising during contract performance. Disputes may end up in court or in a designated board of contract appeals. Some contracts extend for many years, with either annual renewal options, or they are awarded on a multiyear basis. At the conclusion of the contract, it must be closed out so that all outstanding funding and performance issues are resolved.

Separate procedures exist for different types of public procurement, such as when buying architect-engineering services, which uses a qualifications-based selection procedure (known in the federal government as “Brooks Act procedures”) rather than price

competition. Also, most jurisdictions allow the use of simplified procedures for small dollar value purchases. For federal agencies, a transaction of \$100,000 or less may be conducted by requesting quotations over the telephone or by electronic mail, resulting in an abbreviated purchase order rather than a lengthy contract. (This amount increases to \$5 million if the item being purchased is a commercial item sold to the general public.) Federal agencies may place delivery orders under Federal Supply Schedule contracts issued by GSA on a streamlined basis for supplies and services. State and local governments that are interested in cooperative purchasing for information technology items may also use the GSA schedules, as a result of recent legislation. Although the emphasis in public procurement has long been toward greater competition in contracting, noncompetitive contracts may also be awarded, and these are typically subject to higher level approvals than other contracts.

POSITIVE AND NORMATIVE DEFINITIONS

One approach to defining public procurement is to examine what its practitioners do on a daily basis. The body of knowledge defined by GSA’s Federal Acquisition Institute^[4] (FAI) and the various professional associations in public procurement can be considered a positive approach to what public procurement is. Johnson, Leenders, and McCue^[5] describe the results of a survey of governmental purchasing groups in terms of organizational structure, responsibilities, reporting relationships, team-based procurement, and involvement in major organizational activities. The authors found significant differences in the responsibilities of public procurement buyers in the supply chain, namely, there was a lower level of involvement in the planning process as well as risk management by public sector procurement officials than their private sector counterparts.

Discussion of public procurement often involves opinion as to what public procurement “should” be, as noted by various commentators:

Public Procurement as Business

One common thread in all public procurement is that it is carried out by obtaining needed items from businesses. Recent commentators such as Rindner^[6] have advocated the view that “acquisition is business” by highlighting the need for public procurement professionals to understand the commercial marketplace, become customer focused, maintain relationships with customers, and expand their ability to draft requirements or manage programs. The notion of the public

procurement practitioner as “business advisor” or “business manager” has grown considerably in recent years. To a certain extent, public procurement is now facing up to the challenge posed to private sector procurement by Kraljic^[7] much earlier when he argued for a greater role of procurement in supply chain management. As a related development, federal legislation has promoted both the acquisition of commercial items and the adoption of procurement practices more similar to those used by private sector businesses (FAR Part 12). The US federal government may now use simplified procedures for buying commercial supplies and services up to \$5 million (increased from \$100,000 in 1994), and buyers are encouraged to look to the private sector when developing terms and conditions for federal contracts, rather than using government-unique specifications.

Transactions, Systems, and Process-Based Approaches

Public procurement has been defined in terms of its means of handling specific purchase transactions or “making the buy.” The goal in recent years has been to move beyond viewing this transaction processing as a clerical function, but instead to view it in terms of the efficiencies that public procurement can offer. Especially in the area of procurement of supplies, public procurement has the potential to find quantity discounts and to provide data and analysis of spending patterns to identify opportunities for improvement.

In other respects, public procurement has been regarded as a process-based approach to government. The amount of law and regulation governing how public procurement is conducted is staggering. For federal agencies alone, the FAR prescribes in great detail the procedural rules for how supplies and services must be bought. In fact, the overabundance of rules has caused some to draw attention to the need to focus on results rather than simply the process of contracting.

Another view of public procurement is to consider it as a “nested structure of systems within systems,”^[8] such as the rulemaking system for public procurement at the federal level as typified by the voluminous FAR rules, the procurement cycle for how buys are made, and the organizational structure involved (requiring office, procurement office, receiving/inspection office, etc.).

PROFESSIONALISM

Professional Associations

The dominant professional associations for buyers who work for government organizations are the

National Institute of Governmental Purchasing (NIGP), the National Contract Management Association (NCMA), and the National Association of State Procurement Officials (NASPO). All members of these organizations arguably do the same kind of work, despite the differences in terminology or definition. Periodicals issued by various organizations involved in the field likewise reflect the diversity of terms for the buying done by governmental organizations. The American Bar Association issues *Public Contract Law Journal*, NCMA prints *Contract Management*, the Department of Defense has published *Acquisition Review Quarterly*, a popular web site used by practitioners is called “Where in Federal Contracting?” (www.wifcon.com), and there is a *Journal of Public Procurement* published by Florida Atlantic University.

Lately, professional organizations for public procurement practitioners have sought to expand the reach and influence of the discipline. For example, NCMA^[9] offers the following definition:

“Contract management is a strategic management discipline employed by both buyers and sellers whose objectives are to manage customer and supplier expectations and relationships, control risk and cost, and contribute to organizational profitability/success.”

Similarly, NASPO^[10] has broadened its view of the role played by public procurement, noting: “The emphasis is shifting rapidly from just a “buy transaction” to supply chain management, which includes the requirement definition and disciplines such as supplier development and global sourcing.” This is part of a transition “from process-based to knowledge/accountability-based procurement organizations.”

Public Procurement as a Profession

The NIGP and NCMA refer to a body of knowledge that those working in public procurement should possess. Federal Acquisition Institute has developed “Contract Specialist Training Blueprints” to define, in terms of daily work, what public procurement professionals do. There are 71 different critical tasks and duties performed in public procurement, grouped into three phases: acquisition planning, contract formation, and contract administration. Examples of some of the 71 common tasks or duties are market research, negotiation strategy, and contract modification. Similarly, NCMA has developed a “Contract Management Body of Knowledge” used for its certification program for members who pass a rigorous examination leading to professional designation. National Institute of Governmental Purchasing also has two different certification programs intended to

“indicate to the public that, having mastered a body of knowledge, one can make sound decisions that reflect maximum value for the taxpayer’s dollar.”^[11]

CONCLUSIONS

Overall, public procurement is one of the most significant areas of governmental activity in terms of money. It is also one of the most highly regulated fields of government endeavor. Although there is no single definition of public procurement, and commentators are fond of saying what public procurement should be, the themes of working with customers to define requirements, publicizing upcoming procurements, soliciting and awarding contracts, and administering those instruments are common to all forms of public procurement. In the future, an expansion of the role of public procurement is likely as its strategic role is increasingly recognized.

Public Procurement Ethics

David Seth Jones

Department of Public Policy, University of Brunei Darussalam, Gadong, Brunei

INTRODUCTION

One of the hallmarks of good governance in the modern state is adherence to strict ethical standards by government departments and agencies in procuring goods and services for public programs (these organizations are commonly referred to as government procurement entities or GPEs). Such standards are necessary for several reasons. The procurement of goods and services by public authorities often comprises a significant percentage of both the operating and capital budgets of a government and involves spending a substantial part of the revenue provided by the taxpayer. In addition, how public procurement is undertaken has a crucial impact upon the efficiency and effectiveness of public services and may also affect growth and employment within the wider domestic economy. For ethical principles to be upheld, there should exist a clear framework of rules and procedures based upon them, governing the various stages of the procurement process: devising specifications, advertising the intended procurement, evaluation of tender and quotation submissions, recommendation of a submission, final selection, drafting the contract, and post-contract adjustment.^[1] Where they exist, such rules and procedures are usually enshrined in legislation and/or stipulated in administrative directives, often contained in public service operational manuals, with which procurement officers and other public officials as well as suppliers must comply.^[2,3] Explained below are the key principles upon which such a framework of procurement should be based.

FAIRNESS

Principles of Fairness

An important part of the ethical responsibility of government and GPEs when purchasing goods and services is to follow fair practices. Fairness can be construed in various senses: rewarding desert, providing for need, avoiding harm to others, and honoring a promise. In the first sense, it entails providing rewards according to merit, achievement, or endeavor. In the second sense, it involves responding to the needs

arising from circumstances or inborn disadvantages, regardless of merit, achievement, or endeavor.^[4,5]

These two interpretations of fairness have given rise to two different approaches to public procurement. The third interpretation of fairness prohibits actions which harm the legitimate interests of others, while the fourth sense of fairness, based on the duty to keep a promise, requires that the terms of a contract, freely entered into, be honored by the parties concerned.^[6]

Desert Principle: Equal Access

Fairness related to desert requires that all potential suppliers be given equal access to the public procurement market through open competition, and that contracts be awarded to those who offer the lowest price or best meet the stipulated specifications.^[2,7] To ensure equal access and a level-playing field, governments and GPEs must disseminate information about an intended procurement as widely as possible through the relevant advertising channels: the government gazette, the local and overseas newspapers, the trade journals, and, increasingly, the internet.^[8,9] Equal access also necessitates, for the benefit of overseas companies and businesses, that a reasonable time be allowed for both the receipt of tender and quotation forms and other detailed documentation and also the submission of tender and quotation proposals. Once tenders and quotations have been submitted, the GPE is obliged to objectively evaluate the merits of each in terms of price and specification fulfillment to determine which proposal is the most advantageous.^[7-9]

After the contract has been awarded, fairness based on desert prescribes that unsuccessful tenderers be informed of the reasons why they have failed. This would be helpful in enabling them to submit better proposals for future tenders and quotations. In addition, in the interest of fairness, any unsuccessful tenderer who has grounds to believe that his/her submission was not evaluated on the basis of merit or that procurement officers did not follow official procurement procedures should be given the right of appeal to a procurement adjudication body.^[3,8]

Furthermore, postcontract adjustment should be carefully limited.^[3] For contracts that extend over a lengthy period, some adjustments may be necessary

as a result of changing rates of inflation, currency fluctuations (for overseas suppliers), newly improved product designs, and changing needs of the GPE itself. The contract alterations may be negotiated with the contracted supplier and should only be allowed under conditions stipulated in the contract or with the agreement of both parties. However, where the postcontract adjustments are either unrelated to the above and/or are substantial, then it is only fair to other potential suppliers that a new tender or quotation be called for.^[3]

Open competition based on equal access has been enshrined as a central principle in the WTO's Government Procurement Agreement (GPA), which was drafted in 1994. More than 30 countries are now signatories to the agreement. The key objective is to liberalize the public procurement market in as many countries as possible and so enable foreign suppliers or foreign-linked suppliers to compete for government contracts on equal terms with local suppliers. Governments which acceded to the GPA cannot, under its provisions, discriminate against foreign suppliers, even those that do not include any domestic content in the their goods and services, nor can they discriminate against local suppliers with foreign affiliation or ownership and/or trading in goods and services originating in another country.^[8] Goods and services of a security or strategic interest may be exempted (e.g., construction of a military building). In this respect, the GPA has followed the system of competitive procurement adopted in the European Union based on EU Directives following the creation of the European Single Market in 1987.^[7,10,11]

Need Principle: Unequal Access

Alternatively, public procurement practices may be considered as fair if suppliers are chosen on the basis of their needs (or the needs of the population or section of the population to which they belong). Such suppliers are then given preferential treatment with contracts drafted which take into account those needs. Included in this category may be local suppliers within the country, small-scale suppliers, and those drawn from disadvantaged minority communities, most of whom could not compete effectively for government procurement contracts if equal access through open competition was permitted.^[7,12] Affirmative access, it is argued, is necessary to enable such businesses to survive and expand and to generate income for owners and employees alike. For suppliers from a minority community, affirmative access may be important in raising living standards and creating business opportunities as part of a wider policy to improve its circumstances. To facilitate affirmative access, selective

tendering may be adopted which restricts tender submissions to suppliers that fall within the categories stated above. To the same end, open tendering may still be adopted, but with special consideration given to submissions from the favored categories during the evaluation stage.^[2,12] Such special consideration may entail allowing a preferential percentage margin on the prices offered by the suppliers concerned.

Avoidance of Harm Principle

Fairness also imposes a responsibility upon GPEs and suppliers to ensure that goods and services are produced or supplied by means that do not lead to harmful consequences for others (negative externalities), especially in terms of health and safety. Examples of such externalities are the production of goods in which little care is taken to protect the safety of employees or which results in environmental waste or pollution. It is then justified for GPEs to restrict access to the public procurement market for businesses engaged in such practices. For this reason, certain governments, as a matter of principle, discriminate against businesses with poor industrial safety records or which despoil the environment or do not supply environmentally friendly products.^[13,14]

Principle of Contractual Obligation

It is only fair, in accordance with the moral duty to keep a promise, that once a GPE and a supplier have signed a procurement contract, both then honor its terms. During the period of the contract, the GPE might want to alter the terms of the procurement, as a result of its changing needs, as mentioned above. This might be allowed under certain conditions and within certain limits, which should be stipulated in the contract. However, fairness dictates that, having entered the contract, the GPE should secure the agreement of the supplier to an alteration of the terms beyond what is allowable and should not terminate the contract if this is not forthcoming. Likewise, the supplier is duty-bound to honor his/her obligations under the terms of the contract, and any adjustment it wishes to make must have the consent of the GPE.^[9] The key obligations for suppliers that relate to honoring a contract include not committing a novation of contract, refraining from unauthorized subcontracting, meeting the specifications in the type and quality of goods and services supplied, adhering to the price agreed, and abiding by the stipulated time frame for delivery.^[9,15] Where the supplier is in serious default of the above, the GPE has the right to impose penalties, e.g., fines, termination of contract, and debarment from future contracts.

VALUE-FOR-MONEY

As major spenders of tax revenue, GPEs are under an obligation to provide value-for-money for the public as both taxpayers and recipients of public services. This reflects the “social contract” at the heart of a democratic state, by which voters/taxpayers are entitled to receive from an elected government efficient and effective public services in return for the income and wealth they have foregone through taxation.^[7,16]

Value-for-money is achieved through the procurement of goods and services for a public program, appropriate to its specific requirements, which are of a sufficiently high standard and purchased at a reasonably low price. If such criteria are not adhered to, the taxpayers’s money will be wastefully spent and public managers will be denied the means of providing a high standard of public services. Ensuring that a procurement meets the requirements of a public program may necessitate decentralizing the task of procurement to the implementing department or agency. However, where materials are commonly used in a standard form by all departments and agencies, then value-for-money can best be guaranteed by bulk purchasing by a centralized body.^[1]

To ensure value-for-money, certain procedures must be established and observed. These include justifying the need for the procurement and devising procurement specifications in light of program requirements. In addition, tender proposals should be thoroughly vetted to determine which is the most advantageous, and contracts should be properly and precisely drafted. It is also important that procurement decisions are taken by committees and bodies that include not only procurement officers, but also technical specialists with the expertise to understand technical specifications and the end users who can determine if the products and services to be procured are appropriate to their programs.^[7]

In most cases, value-for-money is most likely to be achieved through open competitive tendering. However, sometimes, even selective tendering and limited sourcing can result in equally positive outcomes. This depends upon negotiation and hard bargaining by procurement officers on matters of price, design, scope, and quality of the product or service to be purchased.^[7] In such cases, procurement officers will be aided by having access to full information of the prospective supplier’s cost breakdown, expected profit margin, and supply capacity.^[17–19] Limited sourcing may involve the use of just one supplier for repeat procurements of the same goods or services. This is justified if the supplier is reliable and, on the basis of a guarantee of repeat orders, is prepared to offer discounts and improved products and services, resulting in better value-for-money.^[11,19]

PROBITY

A further ethical obligation of governments and GPEs is to maintain strict standards of probity and avoid corruption and dishonesty in the procurement of goods and services. All too often, public procurement is undermined by corrupt practices in which political leaders, senior administrators, procurement officers, and other officials take advantage of the opportunities provided to make illicit personal gains or secure benefits for their family and friends. All the main forms of corruption can occur. One is misappropriation in which suppliers are overinvoiced and provide more goods than needed or specified, with the surplus then falling into the hands of public officials and used for their benefit or sold for personal gain. Another prevalent form of corruption is bribery. Money and favors (kickbacks) are offered to, or demanded by, officials in return for the award of a contract.^[2,9,15] Equally common is nepotism and cronyism by which preferential treatment is accorded to businesses linked to the families and friends of government officials who influence or decide the choice of tenderer.^[20] For their part, suppliers may act unethically not only by offering bribes, but also by committing fraud, such as by deliberately disclosing false information about their past financial record, resources and capital value, and their capacity to deliver the goods and services in question.^[9]

To ensure high standards of probity, measures may be enforced to both prevent and deter corruption and dishonesty. Preventive measures may include a requirement that officers who are involved in any significant stage in the procurement process declare any possible conflict of interest. This especially applies to a personal or family connection with a business (or any affiliated business) submitting a quotation or tender, through ownership, partnership, shareholding, and loans.^[9,20] As further measures to prevent corruption, the different functions and stages of the procurement process should involve separate officers (including separate officers for making procurement policy and undertaking procurement operations), and if manpower availability permits, they should be rotated on a regular basis.^[2] In addition, more than one officer should be involved in the key stages of the procurement process.

Preventive measures should be reinforced by deterrence measures to punish those discovered to be engaged in corruption and dishonesty. Penalties would include stiff fines; in more serious cases, prison terms; in addition, for suppliers, debarment from future contracts; and for procurement officers, demotion or dismissal from post. In some countries such as Hong Kong and Singapore, legislation has been enacted under which an anticorruption agency has been created with wide-ranging powers to pursue inquiries and unearth any evidence of corrupt practices, with courts

given powers to pass stiff sentences in such cases.^[21] In many countries, the government audit agency is given the investigative powers and the responsibility to identify corruption in the procurement process.

TRANSPARENCY

Maintaining fairness, value-for-money, and probity in part depends upon making the public procurement process as transparent as possible. This requires the disclosure of all relevant information at critical points in the process.^[3] At the outset, information relating to an intended procurement, including tender or quotation specifications, should be made available to all prospective suppliers, as mentioned above. The various tender or quotation proposals submitted should then be publicized, followed by the disclosure of the name of the successful bidder, together with the content of the contract and the cost of the purchase.^[3] Transparency also requires that reasons be given to the unsuccessful tenderers why they had not been selected, as stated above. In addition, to ensure proper accountability in the procurement process, government auditors, internal regulatory authorities, and relevant watchdog committees within the legislature should be given details of how a procurement was undertaken, together with all the necessary documentation, if so requested. Where necessary, senior administrators and procurement officers of a GPE should be subject to cross-examination by relevant committees of the legislature.

Transparency underpins the three other ethical principles in public procurement in two senses. First, it is an essential condition in enabling open competition for tenders to prevail which is both the basis of fairness related to desert and arguably a guarantee of value-for-money. Second, it subjects GPEs to greater scrutiny and accountability in respect to various aspects of fairness, value-for-money, and probity. Any deviation from such standards can be readily identified and exposed, allowing action to be taken to rectify the shortcoming.

CONCLUSION

The above principles governing procurement in many respects supplement each other. For example, measures that promote fairness based on open competition necessitate transparency, arguably ensure increased value-for-money, and even safeguard standards of probity. Value-for-money is more likely to be achieved with greater transparency that allows procurements to be open to scrutiny leading to greater political and public accountability. Value-for-money can be further enhanced if procurement practices are governed by

probity, in view of the fact that corruption can lead to a lower standard of procurement and greater waste and inefficiency.

However, in one respect, one of the principles of procurement may be at variance with the others. While much may be said in favor of fairness based on the need to allow unequal access to the public procurement market, this may lessen the possibility of achieving value-for-money because the suppliers chosen for a contract through special preference may not offer the most advantageous terms. Equally, it may be at variance with fairness based on open competition and merit because suppliers offering better terms and more capable of meeting the specification requirements may be rejected. This requires the government or GPE to determine where the balance of ethical responsibility lies between need and value-for-money. If consideration of need-based fairness in the procurement process does not result in the acquisition of substandard goods and services at an excessive price to the taxpayer, then preferential access may be allowable. However, if such access does indeed lead to procurements that fall well short of giving value-for-money, so impairing public programs and excessively draining tax revenue, then the alternative of selecting the best suppliers through open competition within a level-playing field may be the better option.

Public Reporting

Mordecai Lee

Department of Governmental Affairs, University of Wisconsin-Milwaukee,
Milwaukee, Wisconsin, U.S.A.

INTRODUCTION

Public reporting refers to the actions of a government agency to account to the citizenry for its activities in the recent past, including its record of performance and its stewardship of public funds. The term refers both to the normative obligation of public entities in a democracy to perform such activities and to the internal management activities necessary to accomplish this external communications goal.

Public reporting was developed by public administration theorists in the first half of the 20th century in an effort to harmonize the emergence of the administrative state with democracy. Inasmuch as permanent and professionalized bureaucracies were not subject to elections, there was a need to define the role of public administration in democracy. By assigning to senior civil servants the duty to report directly to the citizenry on agency activities, theorists sought to make government departments accountable to the public-at-large, not just to elected officials. Public reporting would contribute to an informed citizenry, the ultimate source of power and decision making in democracy.

ORIGINS

With the emergence of the administrative state in advanced western societies in the late 19th and early 20th centuries, a natural concern arose regarding the need to harmonize democracy with the inherently undemocratic nature of bureaucracy. Political, legal, and constitutional responses were the understandable initial solutions. Administrative agencies would be formally accountable to the elected and appointed oversight institutions of democracy, such as through budget and policy controls possessed by the chief elected executive officer, oversight activities by legislative bodies, and the jurisdiction of the courts to rule on agency policies and procedures. These elected and appointed constitutional branches of government would be able to assure that democracy would reach into bureaucracy through external controls and interventions. Yet these approaches all assumed that

bureaucracies were only *indirectly* accountable to the citizenry—the source of democratic sovereignty and power.

However, another line of thinking suggested that bureaucracies also needed to be *directly* accountable to the voters. It was not enough, this theorizing went, to be accountable to the citizenry through other democratic institutions. Instead, agencies should also be directly responsible to the electorate. Thus was born public reporting.

As it gradually developed in the 1920s and 1930s in the United States, public reporting referred to the duty of the public administrator to report regularly to the public-at-large on the activities of the agency. Inasmuch as an informed public was the sine qua non of democracy,^[1] then government agencies should be one of the sources of information for the citizenry about the operations of the public sector. For public opinion to be the central engine of decision making in a democracy, the voters needed to have basic information upon which to construct their opinions. In the administrative state, information should come not only from traditional sources, such as newspapers, civic groups, and elected officials, but also from the newest component of the public sector, government departments. That meant government managers had the obligation of preparing and releasing reports on a regular schedule, helping to assure that the public would become familiar with agency activities.^[2–4]

Public reporting first emerged as part of the efforts by reformers to “clean up” American city governments in the early 20th century. A knowledgeable citizenry would become a bulwark against patronage, waste, and corruption in city halls. One of the first references to public reporting was in 1912, when Bruère^[5] argued that the concept of “efficient citizenship” required regular reporting by city government to the public. In the 1930s, the International City Management Association sponsored contests to promote improved public reporting^[6] and through the 1950s continued actively encouraging municipalities to conduct robust reporting programs.^[7]

The public reporting imperative of the government manager is one of the activities that operationalizes the difference between business and public administration.

Given the public-sector environment it operates in, government management is qualitatively a different activity from business administration. The duty of public reporting is one of the components of public administration that reflects this inherent intersectorial difference.^[8]

DEFINITION

Public reporting is only one element of the array of interactions that government agencies have with the public-at-large. In that respect, it needs to be delineated in a way that clearly separates it from other related, but distinctly different, activities.

In the context of an agency's external communication programs, public reporting is an activity that is not related to the efficient implementation of the agency's core mission. Many public relations programs are aimed at furthering the *raison d'être* of an agency, such as informing the public of new programs and services, using publicity as a substitute for regulation and encouraging the public to serve as the "eyes and ears" of the agency.^[9] In that respect, public reporting is a communication activity that does not "do" anything in context of the pragmatic get-the-job-done pressures of daily management and communications. Rather, reporting simply provides information for information sake.

Similarly, public reporting focuses on efforts to contribute to an informed public. In that sense, reporting contributes to the functioning of democracy. However, public reporting focuses only on the transmission of information from the administrative agency to the public and not on the subsequent developments that it triggers. Thus public reporting is different from citizen participation in agency decision making or agency "listening" to customers and clients in an effort to improve the quality of consumer interactions.

Given that the modern definition of communication is a two-way flow of information, then public reporting focuses solely on the first half and front end of the entire communications loop and only on communication intended to inform for democratic purposes. Therefore public reporting is defined as:

the management activity intended to convey systematically and regularly information about government operations, in order to promote an informed citizenry in a democracy and accountability to public opinion. It consists of direct and indirect reporting of the government's record of accomplishments and stewardship of the taxpayers' money. Public reporting is presented in many different communication formats, but always uses vocabulary that is understandable and meaningful to lay citizens.^[10]

Public reporting occurs when an agency conveys information about its performance to the citizenry rather than to political and elected oversight institutions. Certainly, public opinion gains information about the operations of the government from elected officials, whether those from the executive or the legislative branches. However, the central concept of reporting focuses on government agencies communicating with the public *besides* the formal, legal, and constitutional channels they are subject to.

Generally, a bureaucracy can report to the public in two ways: directly and indirectly. Indirect reporting refers to communication efforts *through* the intermediary institution of the news media. Direct reporting focuses on non-mediated communications from the agency to the public-at-large for the purpose of conveying summary and performance information.

INDIRECT REPORTING

One way for an agency to inform the public is by facilitating media coverage of its operations. As an instrument of democracy, the news media can provide the public with ongoing information about the activities and performance of the government. Given this constitutional role of the press in contributing to an informed citizenry, agencies have a counterpart obligation to assist the press in its efforts to report about agency operations. This perspective is the underlying rationale for public-sector agencies to maintain media liaison offices, staffed with specialists trained in dealing with reporters.

Some news coverage of an agency is headline-driven. In those situations, the agency is passively reacting to inquiries from the press. This form of interaction rarely leads to providing the public with a more systematic and comprehensive understanding of agency performance. Instead, it provides highly selective—and often negative—snapshots driven by the media's need for controversy. Therefore a better opportunity for indirect reporting occurs when an agency is able to initiate and generate coverage. Events such as observing a milestone in a program's operations, the ribbon cutting at a new site, and the kickoff of a new service all provide an opportunity to report indirectly to the public about the general and overall activities of an agency. While, by necessity, an incomplete snapshot of the entire agency's operations, this category of news coverage is nonetheless a channel for reporting to the citizenry on the more routine and daily aspects of government, in contradistinction to news coverage that is crisis- and controversy-driven.

One of the advantages of indirect reporting is that it is free. The agency incurs no additional cost when

the media reports to the public about it. Yet while agencies should make efforts to “tell their story” to the citizenry via the news media, indirect reporting—by itself—is rarely adequate to accomplish the broad democratic goals intended for public reporting.

DIRECT REPORTING

The more prominent and effective approach to public reporting is through direct contact with the citizenry. In the predigital era when public reporting first began, direct reporting often focused on printed materials. Items such as annual and quarterly reports were viewed as one of the basic ways that agencies could inform the public about their accomplishments. Two key elements have been identified as necessary for effective printed reports: contents and distribution.

First, printed reports should be prepared with the audience of the lay public in mind. Reports need to be in plain English and must focus on the key items that represent the agency’s accomplishments. Long and detailed descriptions, use of technical jargon, and impenetrable statistical presentations are examples of what a good report should not contain. Besides use of plain language, effective public reports extensively rely on graphics, photos, and other visual techniques to make the documents user-friendly. Similarly, linking agency information to comparisons that are understandable to average citizens (“for the cost of an average breakfast, our agency delivers to each of our clients . . .”) is another way to contribute to an effective public report. This focus on content and presentation also helps highlight the difference between public reporting and financial reporting. Annual reports prepared by accountants and auditors to satisfy various legal and constitutional requirements rarely qualify as public reporting. The density of numerical information in financial reports generally precludes creating a product that is meaningful to a lay reader.

Second, effective reporting also requires significant efforts to disseminate reports as broadly as possible. Some agencies indeed prepare annual reports, but their dissemination efforts are half-hearted and incomplete. Certainly, copies should be sent to elected officials, key civic leaders, the media, public libraries, and major civic groups. However, the concept of public reporting calls for efforts to put the report directly in the hands of the citizenry. In the middle of the 20th century, municipalities experimented with a wide variety of dissemination channels. Some examples included inserting the annual report in the annual property tax bill or in quarterly bills from municipal utilities, inserting the report in the daily newspaper, having sanitation workers distribute the reports while on their rounds and recruiting boy and girl scout troops to

adopt, as their civic project, the distribution of the report door-to-door.

However, annual reports and other regularly issued publications (such as quarterly ones) are not the only way that government agencies can engage in direct public reporting. Referring again to examples from the mid-20th century, other efforts included open houses, speakers bureaus, billboards, signs on subways and buses, annual exhibits keyed to the budget adoption process, movie shorts, public service advertising, regular radio programs, and film versions of annual reports. Like other marketing and advertising efforts, multiple products and channels need to be utilized to maximize the potential of reaching as much of the citizenry as possible.

ROOSEVELT’S OFFICE OF GOVERNMENT REPORTS

In the federal government, the high water mark of traditional public reporting was the Office of Government Reports (OGR), which President Roosevelt established in 1939. In the Executive Order creating it, one of its central missions was to “distribute information concerning the purposes and activities of executive departments and agencies.”^[11] Roosevelt viewed OGR as the executive branch’s agency that would report to the public on the activities of the federal government. In a national radio address, Roosevelt explained that once informed factually of the record of the Administration, public opinion could then express its will to Congress regarding the continuation or cessation of those federal programs.^[11] As a reflection of the importance he assigned to OGR, Roosevelt made it one of the five original agencies comprising the Executive Office of the President (EOP), which he also established in 1939. However, OGR was a very controversial agency, especially with the conservative coalition in Congress. Overcoming strong resistance on Capitol Hill to the concept of such a federal reporting agency, in 1941, Roosevelt succeeded in shepherding through Congress a law authorizing permanent appropriations for OGR.^[12] However, continued opposition to OGR by legislators forced Roosevelt in 1942 to merge it for the duration of World War II into the temporary Office of War Information (OWI). When President Truman tried to reestablish OGR after the war, as Roosevelt had intended, the Republican 80th Congress refused to appropriate any additional funding for it. OGR went out of existence in 1948.^[12]

The political blowout relating to OGR presented a high-profile case of how easily public reporting can become politically controversial. Whether an accurate assessment or not, the lesson learned was that for public reporting to occur, it needed to be blander and less

engaging. In fact, for the second half of the 20th century, public reporting gradually ossified into boring annual reports at most levels of government. Those half-hearted reports were given limited circulation and triggered even less interest.

21ST CENTURY TRANSFORMATION: E-REPORTING

While the rationale for public reporting retained its validity in the post-OGR era of the second half of the 20th century, as a concrete activity, it gradually faded from prominence in both public administration theory and practice. However, the emergence of the communications age and the digital era has provided an opportunity to revive and reestablish the value of public reporting in the 21st century. New communications technologies now permit government agencies to communicate quickly, efficiently, and inexpensively directly to the citizenry. Annual and special reports posted on agency websites and distributed by e-mail provide an opportunity to perform public reporting in ways that could not have been envisioned a century earlier.

Similarly, the increased attention in public administration to performance measurement has provided a new format by which agencies can report on their operations to the public-at-large. While performance measurement was originally developed largely for management control purposes—whether for the senior management of the agency or for oversight by the executive and by the legislative branch—it has much potential and value to the lay citizenry as well.

Therefore the combination of digital technology with the focus on performance measurement has provided an opportunity to reformulate and reinvigorate the original conception of public reporting. Now called e-reporting, it consists of:

the administrative activity that uses electronic government technology for digital delivery of public reports that are largely based on performance information. E-reporting is a tool of e-democracy that conveys systematically and regularly information about government operations that is valuable to the public-at-large, in order to promote an informed citizenry in a democracy and accountability to public opinion. E-reports are planned to be citizen-friendly, by being understandable and meaningful to the lay public.^[10]

CONCLUSION

Public reporting has been making a comeback in public administration. Herzlinger^[13] has suggested that

one of the ways to restore public trust in government is through improved reporting. That would include an increase in the amount of important information disclosed to the citizenry as well as better and broader dissemination of such regular reports. The Organisation for Economic Cooperation and Development (OECD), an association of the most developed western countries, issued two reports in 2001 calling for improved public reporting and providing guidelines for such efforts.^[14,15]

Whether widely or well practiced, public reporting is a permanent and inherent element of public administration in a democracy. Civil servants are expected to engage in systematic efforts to report to the citizenry on their agencies' activities, performance, and stewardship of taxpayer funds. The profession of public management entails more than effectively running an agency. It also involves contributing to the working of democracy. Public reporting is the vehicle for such efforts. For more information, see Refs.^[16–20]

Public Sector Productivity: Barriers

David N. Ammons

*Institute of Government, University of North Carolina at Chapel Hill,
Chapel Hill, North Carolina, U.S.A.*

INTRODUCTION

Successful managers of public sector organizations find ways to cope with a host of obstacles that jeopardize the efficiency and effectiveness of their operations. Ideally, they devise strategies to circumvent or defeat these barriers to public sector productivity.

Some impediments to organizational performance are common across sectors, confronting public and private sector managers alike, but other barriers faced by public sector managers are distinctive. Common barriers to productivity improvement in the public sector are sorted into the three clusters noted below and described briefly:^a

- Environmental barriers—including factors that most clearly distinguish the public sector environment from that of the private sector and confound productivity initiatives.
- Organizational barriers—including common characteristics found at varying degrees in public sector organizations.
- Personal barriers—including individual traits, attitudes, and behavior that may influence an administrator's inclination and ability to tackle productivity improvement opportunities.

ENVIRONMENTAL BARRIERS

Although many candidates for public office pledge to run government like a business, once elected most officeholders discover that the public sector environment is, in many ways, less conducive to productivity improvement than is the private sector environment. Among the key environmental barriers are the following:

Absence of Market Pressures: Except in cases of “managed competition” or other relatively rare circumstances that introduce the pressure of market

competition, public sector agencies tend to behave as “unregulated monopolies.”^[1–6] If a public sector agency is to be aggressive, responsive, innovative, and cost conscious, its inspiration typically must come from something other than a competitive market environment.

Political Factors that Influence Decision Making: Unlike the private sector where the financial “bottom line” guides corporate decisions, the public sector is influenced by multiple objectives that often conflict with one another. Political biases, personal whims, and the legislative process often can trump a seemingly more rational and productive strategy.

Public's Lack of Patience with Operational Changes and Lack of Enthusiasm for Gradual Gains: The gains from productivity initiatives usually take time to materialize, but the disruptions to the operational status quo imposed by change often are immediate. Unless quick and substantial improvements are made in the quality or quantity of a given service, affected clientele are apt to rail against productivity-inspired program change, whereas even the cost-conscious public at large, unimpressed by cost-saving benefits of perhaps only pennies a day for individual taxpayers, are unlikely to rally in defense of productivity improvement.

Dominant Preference for the Status Quo: If groups having the power to influence change are generally satisfied with the services provided to their members and see little reason to push changes for the benefit of powerless groups, little encouragement is likely to be generated for experimentation and innovation in service delivery.^[7]

Lack of Political Appeal: As a political cause, improving the quality and efficiency of government services lacks the appeal of promises to resolve social issues, the allure of program expansion or capital improvements, the grand implications of long-range planning and economic development strategy, or the widespread personal implications of tax policy. Policy issues capture the morning headlines and the evening news much more often than do stories of operational successes and failures in routine governmental functions.

Short Time Horizon: Many productivity improvement initiatives are long-term strategies that carry large front-end price tags and the promise of only

^aFor a more extensive discussion of productivity barriers, see Ammons, D.N. Productivity barriers in the public sector. In *Public Productivity Handbook*, 2nd Ed.; Holzer, M., Lee, S.-H., Eds.; Marcel Dekker: New York, 2004; 139–163.

gradual returns on investment. Public officials frequently have a short time horizon for such matters—one that extends only as far as the next election. After all, why incur major expenses and perhaps short-term tax increases that are almost sure to earn the wrath of voters, while producing long-term benefits that may only be enjoyed by one's successor?

Subordination of Efficiency to Secondary Status: In public sector deliberations that pit the values of efficiency, effectiveness, responsiveness, and equity against one another, efficiency frequently loses. Professional associations, employee organizations, client groups, neighborhood associations, and service regulators all constitute formidable interest groups that tend to place efficiency on a level secondary to other goals, if they consider efficiency at all. Not surprisingly, the values that compete with efficiency are often given political and administrative priority.

Other Barriers Common to the Public Sector Environment: Other barriers that distinguish the public sector from the private sector environment include the following:

- Limited options for achieving economies of scale (i.e., options for market expansion typically are more constrained than in the private sector).
- More cumbersome procurement and personnel procedures.
- Legal restrictions and court rulings that can dramatically affect the nature of public services, how these services are delivered, and how they are funded.
- Anti-innovation and antiproduktivity effects of some grants and other intergovernmental programs, especially those that impose rigid prescriptions, limit local discretion, or reward increased local expenditures.
- Intergovernmental mandating of state and local expenditures.

ORGANIZATIONAL BARRIERS

Although less pervasive than the environmental barriers that tend to permeate the public sector, a second category of productivity barriers includes impediments that are sufficiently common in public sector organizations to warrant mention here. These organizational barriers differ widely in their incidence and severity. Each may be a major impediment in some agencies or jurisdictions and relatively insignificant in others.

Bureaucratic Socialization Process: When veteran employees introduce newcomers to the ways of the organization, instructing them on what is expected and "showing them the ropes," the result can be

positive if the culture encourages service and innovation, or it can be extremely damaging if the organization's veterans have lost their zeal for excellence. An organization facing the latter circumstance may find itself staffed with a perpetual cadre of bureaucrats resistant to innovation.

Lack of Accountability: If it is true, as critics claim, that few government managers or employees are held accountable for their actions or for their failures to act, then government operations are being deprived of a fundamental mechanism of direction and control. Without the pressure that comes with accounting for resources and results, many managers are likely to be satisfied with the status quo. Why strive for productivity improvement?

Focus on Outputs Rather than Outcomes: Focusing on their department's activities or workload—its outputs—is far easier for most government managers than trying to track progress on the bigger picture of whether their efforts are achieving positive results. However, keeping an eye on results is what leads top-performing organizations to excellence. Their lower-performing counterparts are unlikely to discover opportunities for productivity gains by focusing simply on maintaining or expanding the activities of their departments.

Perverse Reward System: Too often, governments fail to recognize, promote, or adequately reward managers who find ways to do more with less. Instead, they typically reward managers who have expanded their budgets and increased the number of persons they supervise. Such a reward system discourages the pursuit of greater efficiency.

"Spend it or Lose it" Budget Rules: Because few governments allow their departments or agencies to carry forward to subsequent years all or even a portion of any savings remaining in the current year's budget, many operating officials believe that it is more rational to spend the money than to lose it to the central treasury. Besides, any evidence of residual resources might lead budget officials to cut next year's appropriation. The frequent result of these rules is a rush to make end-of-the-year expenditures for purposes that would not have been considered high priorities earlier in the year.

Other Organizational Barriers: Other organizational barriers that challenge public sector managers include the following:

- Inadequate management commitment to productivity—The support of some managers is more rhetorical than real.
- Barriers to monetary incentive plans—Plans for monetary rewards sometimes confront citizen or legislative objections over cost and appropriateness, and even the opposition of supervisors and some

employees worried that the plan will fall prey to favoritism.

- Union resistance—Unions often push for restrictive work rules and higher wages and oppose initiatives that would reduce the workforce, although exceptions in the form of management–labor cooperation in managed competition and other efforts are also noteworthy.
- Perceived threat to job security—When the term productivity is assumed by the workforce to be a pseudonym for “speed up” or “automation” with an accompanying loss of jobs, employee cooperation can be difficult to secure.
- Excessive layers of middle management.
- Supervisory resistance—Supervisors are ideally situated in the organizational ranks to thwart any productivity improvement initiatives they oppose.
- Ambiguous objectives—This is very much like having no objectives at all.
- Reluctance to abandon—Once in place, even unsuccessful programs die hard.
- Insufficient analytical skills or analytical staffing.
- Inadequate cost-accounting systems.
- Inadequate performance data for one’s own operation and inadequate comparison data from others.
- Inadequate performance evaluation/appraisal.
- Inadequate dissemination of information about successful programs, accompanied by a reluctance to use what *is* known.
- Fragmentation of government—The belief shared by many, but rejected by others, that having a host of small, overlapping governments obscures lines of accountability, promotes unnecessary duplication, and forfeits opportunities for economies of scale.
- Bureaucratic rigidities, including an extreme focus on rules and procedures.
- Fragmented authority and uncertainty about where decisions can be made.
- Turf protecting tactics by entrenched public officials.
- Inadequate research, development, and experimentation with technological improvements and other advances for government operations.
- Requirement of large initial investment for productivity improvement efforts—Major gains often require substantial front-end investments.
- Performance myths confound rational management—Myths, for instance, regarding the inadequacy of one-officer patrol cars and the unsuitability of competitive systems for public services have limited managerial thinking in the past.
- Overselling productivity—Overly ambitious promises made to “sell” a productivity improvement initiative can come back to haunt program officials if program results, although positive, fail to match the promises.

PERSONAL BARRIERS

Some barriers are largely personal in nature. Although often influenced by characteristics of the public sector environment or a given organization, these are obstacles that are more internal to the manager or the manager’s job. Among the key personal barriers are the following:

Inadequate Control of Time/Workday: Most government managers, like their counterparts in the private sector, work long hours. Time constraints and the pressures of competing demands for managerial attention constitute an obstacle to productivity improvement, because they limit the manager’s ability to explore new ideas for operational improvement. For some, the enormous demands on managerial time constitute a major barrier; for others, more adept at time management, including prudent priority setting and the art of effective delegation of duties, the obstacle is somewhat less formidable.

Conceptual Confusion: Confusion over the meaning and ramifications of productivity in the public sector complicates communication, undermines analytical and planning efforts, and limits achievement.^[8] Those who view productivity improvement narrowly, simplistically, or apprehensively restrict opportunities and reduce the likelihood of success. The notions of “more bang for the buck” and “working smarter, not harder” only begin to capture the essence of productivity improvement; equating it to forced speedups or cut-back management captures even less.

Proclivity to “Paralysis by Analysis”: A conscientious administrator or researcher would prefer to base important decisions on logic and thorough analysis of complete data. Unfortunately, the information can never be complete; the analysis can never be perfect. At some point, the productive manager has to move forward with a decision based on careful analysis of good, but rarely perfect or complete, data.^[1] Managers who are unable to move forward following a *conscientious and reasonably complete* analysis may inadvertently lock in place a status quo operation, despite opportunities for improvement. They are paralyzed by the thought that a little more analysis would clarify the decision and reveal an obvious course of action. “Paralysis by analysis” is a self-inflicted malady. In some cases, it is produced by perfectionism; in others, it is merely an avoidance mechanism for an administrator who would prefer not to have to make a difficult recommendation or decision.

Risk Avoidance: Successful risk taking in the public sector offers few of the personal rewards enjoyed by successful entrepreneurs in the private sector. Entrepreneurial public managers who take well-reasoned risks that benefit their government and its citizens are inspired instead by commitment, professionalism, and

their perspective on public service. Because the penalty for risk-taking failure can be substantial, many public executives choose to curb their entrepreneurial efforts. Some observers, in fact, even perceive a “relatively low risk threshold of most public officials.”^[9] Others detect an even more serious barrier than the failure to encourage risk taking, suggesting that “innovative people do not choose careers in the public sector.”^[10] Evidence of entrepreneurial behavior in the public sector shows clearly, however, that some entrepreneurs do choose public service careers.

Managerial Alibis: Public sector managers sometimes blame bureaucratic regulations, civil service restrictions, political forces, and the power of long-standing traditions for their inability to adopt innovations or to make other changes that would correct operational inefficiencies. In many cases, these are merely alibis for the managers’ unwillingness to mount the effort necessary to bring change. Innovative, determined managers find ways to work within legal restrictions, civil service regulations, and other administrative rules, or they find ways to work around or amend them. For these officials, bucking tradition may be difficult but not impossible.

CONCLUSION

All public sector managers confront barriers to productivity improvement. Some are particularly adept at recognizing potential obstacles, assessing their

magnitude, and devising appropriate strategies for neutralizing or circumventing them. These are the managers who are most likely to lead their organizations or departments to greater achievements and higher levels of productivity.

Public Service

Richard A. Loverd

Acton, Massachusetts, U.S.A.

INTRODUCTION

Public service, literally serving the public, can be viewed from several perspectives. On the one hand, it can be considered as a place or “locus of employment . . . embracing all those who work in the public sector.”^[1] Then again, as Elmer Staats has noted, it can also be perceived as “a concept, an attitude, a sense of duty—yes, even a sense of public morality,”^[2] suggesting a public service ethic. In this article, both points of view will be explored.

PUBLIC SERVICE AS A PLACE: THE UNIQUENESS OF PUBLIC SECTOR WORK

Public service is very different from private enterprise, so much so that Wallace Sayre has suggested that “public and private management are alike in all unimportant respects.”^[3] While such a view may be a bit extreme, there are major constraints that uniquely shape public-sector work. In particular, those constraints are reflected in a public environment that is diffuse, political, bureaucratic, and very public.

Diffusion

At base, our system of government was not designed to be manageable; it is purposefully, indeed constitutionally, difficult and diffuse. Such ideas are reflected in the words of Graham Allison when he notes that “In business, the functions of the general management are centralized in a single individual: the Chief Executive Officer (CEO). In contrast, in the U.S. government, the functions of general management are constitutionally spread among competing institutions: the executive, two houses of Congress, and the courts. The constitutional goal was “not to promote efficiency but to preclude the exercise of arbitrary power,” as Justice Brandeis observed.” Moreover, Allison further stresses that, “as *The Federalist Papers* make starkly clear, the aim was to create incentives to compete so as to provide security against a gradual concentration of the several powers in the same branch.” In so doing, “the general management functions concentrated in the CEO of private business are,

by constitutional design, spread in the public sector among a number of competing institutions and thus shared by a number of individuals whose ambitions are set against one another”^[3]. Indeed, with power divided and ambition pitted against ambition, it is sometimes a wonder that the public service works as well as it does!

Politics

The very diffusion of power, pitting ambition against ambition, encourages political activity as public servants try to marshal forces that will help them accomplish tasks, protect prerogatives, and expand their power bases. In addition to the power vested in their formal positions, they might use rules, funds, jobs, expertise, tradition, charisma, information, timing, group pressure, and any number of other power sources to influence those within and around their work settings.

As an especially instructive example, jobs have served as a source of power, particularly political party power, throughout the history of American public service. During the 1800s, from around the time of Presidents Jackson to Garfield, government jobs were viewed as “spoils” or prizes to be given to those who worked for the party and helped victorious candidates win public office. Consequently, partisan service, rather than individual competence, was used as the basis for awarding public jobs; and the jobs themselves were deemed of little importance except as they contributed to party power.

Unfortunately, the spoils system soon became a two-edged sword, sharper on one side than the other. For while it proved helpful to the party leadership, it became quite harmful to the country. Because their jobs tended to last only as long as their party candidates were in office, appointees were tempted to plunder their public trusts for personal gain. Thus, the use of jobs as a political means for enhancing party power came to be associated with a lack of competence and an excess of corruption in the government. And when a disappointed office seeker named Charles Guiteau assassinated President James Garfield in 1881, that use was associated with murder as well. Obviously, something had to be done.

Bureaucratic Behavior

To curb the excesses of party interests and restore some measure of responsibility and competence to public servants, bureaucratic reforms were initiated through legislation, first at the federal level, with the passage of the Civil Service Act of 1883, and soon after by states and localities.

These reforms, by being bureaucratic, stressed the use of a rational-legal rather than a partisan-political approach to public management. In so doing, to use Max Weber's terms, impersonal "calculable rules," rather than personal partisan preferences, were used to provide the basis for uniform, even-handed judgments about public employees; and, with no pejorative overtones intended, public managers were to "go by the book" and see that others did the same within their specified spheres of authority, responsibility, and competence. Indeed, competence itself would be judged on the basis of technical proficiency rather than political affiliation or social status; and, as much as possible, employees would be kept away from the corrupting, debilitating influences of partisan politics.

The bulk of these bureaucratic ideas is included in what has come to be known as the "merit system concept" of civil service reform, a concept that provides the cornerstone for civil service policies and processes. This concept includes three fundamental tenets set forth for civil servants (i.e., public bureaucrats): "First, among the historic principles is recruitment via competitive examinations, or on the basis of job ability or individual competence. A second major principle is absence of arbitrary removals, or relative security of tenure. The third fundamental principle is that of political neutrality in the civil service."^[4] Thus, competent people are selected through open, competitive examinations instead of partisan politics and subsequently protected from politically motivated removal by job tenure. And in exchange for that tenure, they are expected to remain politically neutral by making their competence available to the political party leaders of the day.

It should be noted that while the notions of competence and tenure seem straightforward enough, political neutrality has caused problems from the outset. Might not merit employees be tempted to resist the wishes of the political party machinery, prove unresponsive, and attend to their own bureaucratic machinery instead? Indeed, according to a report by the Committee for Economic Development just such bureaucratic merit system problems have come to pass, including: 1) bureaucratic delays, which prevent the prompt filling of job vacancies; many times leading to the loss of top applicants to other job opportunities; 2) recruitment by personnel offices, which is often slow, unimaginative, and unaggressive; 3) rigid

classification systems, which impede the efficient assignment of work; 4) excessive reliance on written examinations, seniority, and other criteria that have little or no relation to job performance; and 5) a lack of authority available to managers to reward superior performers and discipline or fire non-performers.^[5] All these bureaucratic constraints reflect what Wallace Sayre once tagged as a "triumph of techniques over purpose,"^[6] techniques that, in turn, can heighten inefficiency and unresponsiveness and diminish the executive's capacity to manage.

Publicity

James Forrestal, the nation's first secretary of defense after World War II, once stressed that "the difficulty of government work is that it not only has to be well done, but the public has to be convinced that it is being well done. In other words, there is a necessity both for competence and exposition, and I hold it is extremely difficult to combine the two in the same person."^[7] This need for exposition, to have the public's business openly conducted and judged for all to see, can prove quite challenging to managers in government, particularly those used to the privacy of the business world. In the private sector, far more of its managerial activities are, by definition, private: more internal, less visible, and less subject to public and media scrutiny. By contrast, in the public sector, with instant global communications and an intrusive press, managers can expect to be placed in a goldfish bowl, scrutinized about anything and everything that can or may come their way.

PUBLIC SERVICE AS AN ATTITUDE: THE APPEAL OF PUBLIC SERVICE

Given all of the discomfort inherent in the constraints described above, what stirs people to want to seek public service? Obviously it is much more difficult to manage, more political, less efficient, less financially rewarding and more intrusive than private-sector work. So where lies the appeal?

James Perry and Lois Wise suggest that there are different kinds of motives unique to the public service that draw people and keep them, ones that lean less on comfort and economic prosperity as the main incentives. Instead, such attractions as the opportunity to express loyalty to one's country, to serve the public interest and some greater good, to participate in the making of public policy, to redress inequities, to advocate a special interest, or to commit to a public program are more readily provided through government service.^[1] And it is these types of motivational factors

that need to be emphasized when governments are seeking to attract new employees to their ranks.

Of course, communicating the appeal of public service does not come without its challenges, not the least of which is the degree of confidence the public has in its government, a level of support that has not always been high. For example, from the mid-1960s to the 1990s, an ongoing decline in public confidence in American institutions occurred to the point where only one in four Americans believed that the government would “do what is right.”^[1] This decline in public trust has made it all the more difficult to recruit and retain a high quality public workforce, leading many to choose, and trust, private over public-sector employment.

To remedy such low confidence, expectations need to change outside, as well as within the confines of public employment, a condition that will likely require environmental shifts regarding the way in which the public views its public servants as much as any improvements within the public service itself. To wit: The more the public perceives a need for, and appreciation of, its public servants, the more likely its appeal will rise. Therefore, when events requiring a need for governmental intervention present themselves, if public servants should demonstrate their ability to fill that public need in the most productive and effective way possible, confidence and trust will grow.

Perhaps no better recent example of public service at its best can be cited than its response to the attacks by Muslim terrorists on the Pentagon and the World Trade Center on September 11, 2001. The response by police, fire, and emergency medical teams at the local level, and a host of state and federal agencies at higher levels, was impressive, leading Americans to rethink their relationship with their government and perhaps turn back to, and trust it, once again. Indeed, by October 2001, one *Washington Post*/ABC News poll noted that public confidence in Washington to “do what was right” rose to 64%—“within the range of public confidence in 1964, before the Vietnam protest era.”^[8] A good start for not only renewing confidence but also motivating people to reconsider the appeal of public service.

CONCLUSION

Public service can be analyzed as a place of employment or an attitude. As a place, its uniqueness has been emphasized through examination of the constraints that shape its activities. As an attitude, its appeal has been viewed through consideration of the distinct motives that draw people to want to work in such a place. While the challenges are great, so too can be the rewards. Hopefully, the examples of service demonstrated by public employees during times of need will encourage more of the public to appreciate what they do and lead more potential employees to want to participate in its noble tasks.

Public–Private Partnerships for Economic Development

Steven G. Koven
Stuart C. Strother

School of Urban and Public Affairs, University of Louisville, Louisville, Kentucky, U.S.A.

INTRODUCTION

A public–private partnership is a formal complementary relationship between public and private entities to achieve a common objective. The formal partnership arrangement delineates each partner's roles and responsibilities, states the level of investment and risk of each partner, and describes how financial and non-financial benefits will be distributed between the partners. Although partnerships represent government “power sharing,” they also entail “risk shifting” from government to the private sector. The basic purpose of partnering is “to take advantage of the potential for all parties to gain greater benefit than they could on their own.” When public–private partnerships are created, the overall objective of the partnership is usually to increase jobs, to enhance the numbers of employers in a region, or to revitalize the physical assets of an urban area. This encyclopedia entry delineates various public strategies to achieve growth, privatization models, and future directions of public–private partnerships.

PUBLIC–PRIVATE STRATEGIES TO ACHIEVE GROWTH

State and local public actors enter into partnerships with private organizations to accomplish the objective of economic growth.^[1] Some of the most common objectives of an economic development public–private partnership are to improve the general image of an area and to improve an area's business climate.^[2]

Some public–private partnerships are specifically designed to market their area to outside firms. Surveys indicate that about 40% of U.S. cities engage in marketing their cities, and about 21% of cities partner with private economic development foundations. Private foundations typically engage in activities such as developing promotional materials, establishing Web sites, advertising in the media, hosting special events, and sponsoring trade missions abroad.^[3]

Various strategies are utilized to improve the business climate of an area. In general, these strategies can be placed into categories of: 1) providing direct financial incentives; 2) improving the tax environment;

and 3) providing non-financial incentives.^[4] Each of these strategies involves some type of partnership and agreement between governmental entities and representatives of the private sector. These strategies are reviewed below.

Financial Incentives

Common financial incentives provided by government entities to the private sector include grants and loans. Grants have been a part of American history since its founding. Land grants to railroads and homesteading helped open up the nation's west. The Morrill Act of 1862 subsidized schools that offered instruction in agricultural and mechanical arts. Contemporary examples of federal grant programs include funding for urban renewal, small businesses, community development, and urban development. A federal government agency involved in providing grants to private entities is the Economic Development Administration (EDA). Initially, EDA programs were targeted to depressed rural communities. After the mid-1970s, programs were increasingly directed to urban areas. Public works grants, business loans, technical assistance grants, and grants to assist communities affected by economic dislocations are programs administered by EDA. Communities adept at marketing their needs were more likely than others to gain access to these federal programs.

Public entities provide loans for the private sector. The federal EDA provides loans under a Business Development Loan program. States provide loans to enterprises that promise to enhance economic development. These loans are often targeted for specific purposes. For example, the state of New Jersey targeted loans to firms that promise to locate in low-income/high-unemployment areas. Pennsylvania targeted a proportion of its loans to firms that deal with advanced technology. Alaska and Hawaii offer loans to owners of fishing vessels who are unable to secure conventional financing. Ohio gave priority for loans to businesses already operating in the state.

Public loan programs carry the risk of default and financial loss to taxpayers. This risk is assumed by the public sector in efforts to spur economic growth. Usually, state or local departments of economic

development or industrial development authorities make direct loans. Revolving loan funds recycle payments of outstanding loans to other businesses. In theory, once a revolving loan fund is established, it exists in perpetuity and is self-financing as long as default rates as well as administrative costs are relatively low. Loans are often made by community development loan funds at below-market interest rates to help entrepreneurs start new businesses.

Tax Environment

Tax incentives are often offered to businesses in hopes of attracting major employers or retaining existing firms. Typical incentives offered to businesses include tax abatements, tax exemptions, tax credits, and tax increment financing.

Tax abatements are legal agreements between a government entity and a property owner to forgo taxing some share of assessed real estate value for a given period of time. It is expected that when the abatement period expires, rates will be reapplied, tax revenues will increase, and tax base will be strengthened. Tax abatements are the most popular type of tax incentive. They are often used to encourage economic development in depressed or blighted areas. Tax exemptions refer to reductions in the base upon which taxes are calculated. Businesses may be granted exemptions on corporate income taxes, commodities such as fuel, inventories, land, capital improvements, and equipment. Tax credits directly reduce tax obligations. They are more desirable than tax abatements and tax exemptions because they produce a dollar for dollar reduction in the amount of taxes one pays. Tax credits are often granted for activities (such as investment in new plant and equipment) that will produce long-term benefits for the jurisdiction.

Tax increment financing allows jurisdictions to borrow funds and earmarks increased tax revenues (attributable to improvements made with the borrowed funds) to repay debt. When bonds are fully paid, a tax increment finance district can be dissolved, and the full share of the tax increase is assigned to a jurisdiction's general revenue fund. Proponents of tax increment financing cite the facts that it does not incur out-of-pocket expenses, it does not obligate jurisdictions to raise taxes, and it does not place added obligations on property owners who reside outside the tax increment district. Critics of tax increment financing claim that it bypasses voter approval, it increases the need for essential services that must be paid by citizens living outside the increment district, it is more expensive than general obligation debt, and it subsidizes development that would have been undertaken in the absence of government assistance.

Non-Financial Incentives

Site development, enterprise zones, and human resource development represent non-financial public activities that assist in attracting private development. These activities are not cost-free and are justified in the name of economic development.

State and local governments acquire and improve sites for industrial and commercial use. The object of site development is to attract private firms by offering land at a reduced cost. Capital improvements are often made to land in terms of water and sewer lines, landscaping, lighting, gutters, and curbs. The land is then sold to developers below cost. Jurisdictions provide catalogs of available industrial sites or build infrastructure to suit the needs of the private firm.

Jurisdictions often engage in land banking or the practice of acquiring and improving contiguous parcels of land suitable for development. To construct a land bank, public officials search for underused, underdeveloped, and/or misused properties. Officials catalog properties by size and location, keeping the information up to date for quick reference. Land banking usually requires a substantial amount of funds for purchases. Potential sources of funds include surtaxes on local real estate and the sale of bonds.

Enterprise zones provide tax incentives and regulatory relief to businesses that are willing to locate in a designated zone. Proponents of enterprise zones maintain that lowering taxes and red tape will induce companies to make investments in areas that typically are neglected. Such investments, in theory, can provide employment in declining neighborhoods. Critics of enterprise zones claim that they do not create new jobs but only shuffle jobs from one location to another. Furthermore, enterprise zones tend to benefit large, capital-intensive corporations with high tax liabilities. The public sector loses the tax revenue that would be generated from those large corporations when enterprise zones are created.

Many companies will not invest in areas where the workforce is viewed as inadequate. Inadequacies can be traced to insufficient numbers of the types of workers demanded by the enterprise. To alleviate workforce concerns, jurisdictions often provide customized training. This training is typically provided at the employer's work site or a local community college. Many state and local governments tailor training to the specific needs of the individual firm. In a specific example of an innovative public-private partnership, the commonwealth of Kentucky, colleges in the Louisville area, and the large package-handling firm United Parcel Service joined together in a collaborative arrangement that helped to expand the pool of nightshift part-time package-handling employees.^[5] This partnership assured the retention of the largest employer

in the commonwealth of Kentucky, increased tuition revenue for the participating colleges, and expanded access to education.

General economic development strategies that are discussed above have produced numerous success stories. These success stories generally occur when public leaders alter investment decisions of the private sector through the provision of inducements. An alternative perspective on public-private partnerships is viewed from the lens of service delivery. Government services can be delivered through a myriad of arrangements ranging from mostly public delivery to mostly private. Efforts on the part of public sector leaders to shift the delivery of services to private sector providers represent a major development in American governance. Some of the models that represent shifts from public to private provision of goods and services are described below.

PUBLIC-PRIVATE PARTNERSHIP MODELS FOR SERVICE DELIVERY

The level of collaboration between public and private actors in a partnership varies from case to case. Many public services have traditionally been provided directly by the government with no collaboration with the private sector. Intergovernmental agreements (such as a county and city sharing jail facilities, road maintenance responsibilities, or an airport) represent an example of collaboration between multiple public organizations. But the public sector is increasingly looking to the private sector for partners who can produce public services. Savas^[6] lists 10 service delivery arrangements and ranks them by their degree of privatization or their degree of reliance on market forces. According to Savas,^[6] free market, voluntary service, and self-service arrangements are the ultimate in privatization because they contain the least government involvement. Four other types of service delivery arrangements utilize private-sector production. Ranked in decreasing degrees of privatization, these arrangements include franchises, vouchers, grants, and contracts. Service delivery arrangements that utilize a government producer include government vending, intergovernmental agreements, and government service. Government service is considered to have the lowest level of privatization.

The *free market* provides most ordinary goods and services. Consumers select a producer, which is a private firm and pays the private firm. Government is not involved in the transaction in any significant way. *Voluntary service* is provided through organizations that provide services that ordinarily might be supplied by the public sector. Examples of such services include recreational programs run by sports enthusiasts,

protective patrols run by neighborhood associations, and fire protection provided by volunteer fire departments. *Self-service* is the most basic of all delivery systems. It refers to people providing their own services such as installing burglar alarms in their homes to prevent crime.

Franchises are awarded by governments to private firms who agree to provide a unique public service such as airport operation, utilities, and toll roads. Government gives the firm permission to operate in a specific geographic area, and citizens pay the firm directly for services. *Vouchers* are subsidies given directly to consumers to purchase goods such as food (food stamps) or education (school vouchers). Unlike grants where the government decides which producers get the resources, consumers decide where to spend their vouchers. Job-training vouchers and the G. I. Bill are voucher programs designed to increase human capital and are therefore relevant from an economic development perspective. *Grants* are resources given by government to private firms who can then provide more affordable good or service to citizens. Grants are often subsidies, in the form of money, tax exemptions, tax abatements, or low-cost loans. For economic development, many state and local governments give away land at no cost to new firms. *Contracting* involves government payment to a private entity to provide a specific service. Virtually all governments procure some goods or services by contracting with private firms. Services related to economic development that are often provided by contractors include economic development attraction activity, road and building construction, convention center management, industrial development, and urban planning.

Government vending involves the purchase of goods or services from a governmental agency. An example of government vending is the sale of rights for water, mineral, timber, and grazing on livestock on government-owned land. *Intergovernmental agreements* involve one government hiring another to supply a service. For example, a state may contract with a city or county to provide social services, or a small community may purchase library services from a specialized government unit that was organized to sell services to other governments in the region. *Government service* denotes the delivery of a service by a government unit using its own employees. An example of government services is sanitation service provided by a municipal sanitation department or education provided by the local public school system.^[6]

Infrastructure can also be supplied and delivered through various public-private partnerships. Some partnerships that utilize private sector arrangements to supply infrastructure include lease-build-operate, build-transfer-operate, build-own-operate transfer, and build-own-operate.^[6]

Under *lease-build-operate* partnerships, a private firm is given a long-term lease to develop (with its own funds) and operate a facility. The firm pays a rental fee and reaps a reasonable return on its investment over the term of the lease. The facility remains publicly owned. Under the *build-transfer-operate* partnership, a private firm builds a facility and transfers ownership to a government agency. The government agency then leases the facility back to the private firm. The private firm operates the facility and has the opportunity to recover its investment. The firm earns a reasonable return from user charges and commercial activities.

In the *build-operate-transfer* arrangement, a private developer is awarded a franchise to finance, build, own, and operate a facility and to collect user fees for a specific period of time. At the end of the time period, ownership is transferred to the public sector. In contrast to a sale, government retains control over the project. Under the *build-own-operate* partnership, the private developer finances, builds, owns, and operates a facility in perpetuity under a franchise agreement. Long-term property rights provide a significant financial incentive for capital investment. Examples of build-own-operate transfer arrangements include the construction of a bridge in Shanghai, China, the construction of the “chunnel” under the English Channel, the development of private toll roads in California, and the creation of power plant facilities in Indonesia.^[6,7] The build-own-operate arrangement resembles outright privatization.^[8]

TRENDS AND DIRECTIONS OF PUBLIC-PRIVATE PARTNERSHIPS

The use of public-private partnerships is believed to be on the rise at the start of the 21st century because of partnership's ability to leverage private capital.^[8] Public sector leaders primarily enter into public-private partnerships because “they are seeking additional capital for economic expansion.”^[9] In many instances, partnerships facilitate the construction of worthy goods, allow private sector contractor to make a profit, and permit eventual public sector ownership of facilities without government expenditure.

Another factor contributing to the popularity of public-private partnerships appears to be the decentralization of decision making from the national to local governments. Local governments often lack the fiscal resources necessary for public projects. Therefore creative entrepreneurial approaches, such as partnering with the private sector, are useful to provide needed public goods and services. Partnerships between public and private sector officials offer the promise of increasing efficiencies in the delivery of public services as well as increasing the leveraging of

private sector funds. These private sector funds are utilized for public projects.

A third reason for the rise in partnerships between government and industry relates to structural changes in the economy. In the new marketplace, firms increasingly compete across national boundaries, and public officials have a vested interest in maintaining international competitive advantages. In the United States, with its so-called “New Economy,” economic growth relates to technological advances and corporate strategy.^[10] In efforts to maintain and expand comparative advantages, technology partnerships between public and private actors have evolved.^[11]

A leading example of a high-profile public-private partnership is SEMATECH, a partnership formed in 1987 between U.S. computer-chip makers and the U.S. federal government. Under this partnership, the federal government provided funding for a collaborative effort to increase the computer-chip market share of American companies. At the time of the creation of the SEMATECH, companies based in the United States lagged behind Japanese-based companies in the sale of semiconductors.^[10] After almost a decade, the United States became the world leader in the semiconductor market, and the federal government withdrew public funding for SEMATECH.

A number of factors coalesce to expand the trend toward public-private partnerships. Decentralization of political power, an entrepreneurial public sector management style, fiscal stress, and the need for infrastructure all contribute toward this trend. The use of partnerships is viewed as especially critical in regard to infrastructure creation.^[12]

CONCLUSION

Savas noted that privatization of government functions is in the ascendancy, and that a majority of Americans no longer believe that an expanding state is the answer. He stated that “throughout the world we are experiencing a reorientation of government away from a top-down approach, an abandonment of the reigning assumption that a powerful, active, and interventionist government, manned by a caring intellectual elite and driven by good intentions, is the basis for good society.”^[6] Public-private partnerships are likely to further evolve as acceptance of privatization as a basic strategy for societal governance grows in acceptance.

Some authors, however, caution against the blind acceptance of increased privatization. Rosenau^[13] noted that private and public partnerships may suffer because of conflicting interests. Conflict is attributed to the fact that the private sector is oriented toward profit, risk, competition, and corporate goals, whereas

the public sector is oriented toward legislation, public opinion, democratic decision making, minimizing risk, and realizing social goals. Because of this inherent conflict, policymakers must guard against providing services to vulnerable populations (the children, the elderly, the disabled, and the cognitively impaired) in such a manner as to maximize profit at the expense of quality, access, or equity. In addition, public-private partnerships should avoid cronyism or improper awarding of contracts to private firms who enrich themselves with public resources.^[14] Public-private initiatives that erode participation, equity, access, and democracy concerns must be minimized. In general, however, public-private partnerships have proven to be an effective tool for economic development projects, and it is expected that they will continue to be utilized in the future.

Public–Private Partnerships in Developing Countries

Steven G. Koven
Stuart C. Strother

School of Urban and Public Affairs, University of Louisville, Louisville, Kentucky, U.S.A.

INTRODUCTION

In recent years, developing countries have been embracing innovative methods of service delivery including privatization, quasi-private arrangements, and public–private partnerships. Over time, officials in these nations have come to realize that government initiatives alone cannot properly address the enormous economic and social challenges that they confront. The needs of developing countries are truly vast and are beginning to be addressed through various combinations of partnerships between philanthropic organizations, non-government organizations, corporations, community-based organizations, and government entities.

Partnerships exist in developing countries for an array of activities including health care, transportation, energy policy, technology development, protecting the environment, making agriculture more productive, generating revenue from tourism, and many more activities. These partnerships offer the promise of generating profits for private companies, increasing government revenue, and improving the lives of people who often do not have access to safe water, electricity, or all-season roads.

Leaders in developing countries have come to recognize that government alone has failed to meet developmental goals. In turn, these leaders have begun to look at innovative partnership types in an effort to improve the living conditions of their constituents. This encyclopedia entry will describe why delivery systems such as privatization have grown in popularity, the decline of statist thinking, constraints on effective public–private partnering, and examples of successful partnerships.

WHY PRIVATIZE?

The movement away from monopolistic, government provision of goods and services has steadily advanced since the latter half of the 20th century. Numerous economic and social reasons have been presented to explain events such as the collapse of Soviet as well as Eastern European communism after 1989, the rise of leaders such as Margaret Thatcher in Britain and Ronald Reagan in the United States, and the renewed

acceptance of neoclassical economics in developing countries.

Savas^[1] identified five factors that have propelled the rise of privatization throughout the world. These factors include the impact of 1) pragmatic forces, 2) economic forces, 3) ideological forces, 4) commercial forces, and 5) populist forces. According to Savas, pragmatic forces promote privatization because there exists a need to continuously provide services to constituents in environments of rising costs and resistance to higher taxes. It is believed that privatization can assuage these pressures by enhancing productivity, reducing waste, and promoting efficiency. Productivity may be enhanced in a variety of manners. In instances where government-owned enterprises are dominant, they can be forced to compete with private companies. Competition between public and private entities can transpire for government contracts or for satisfying consumer desires. Economic forces that promote privatization relate to a growing affluence in some parts of the world and affluence's corollary of less dependence on government. For example, if more people own their own automobiles, there will be less reliance on public transportation.

Ideologically, some political theorists see an expanding government sector as a threat to freedom and liberty. This threat to individuals has been well documented historically. Nations such as Germany (during the Nazi regime of Adolf Hitler) and Russia (after the 1917 Bolshevik revolution) witnessed the growth of massive state entities that exercised almost total control over the lives of individuals. It is therefore not surprising that individuals living in pluralistic societies are wary about ceding power to impersonal government institutions. People in developing countries have often found themselves in situations where their individual rights were subsumed to a collective ideal that was defined by the state. Seizure of private property often preceded tight, central control over the economy, an economic paradigm that recently has been discredited.

Countries with large nationalized interests may also be pressured by business leaders to provide more business opportunities to private citizens (commercial forces). Savas^[2] noted that much of the work performed by government consists of routine commercial activities such as maintenance of buildings, grounds,

vehicles, and ships, data processing, collecting trash, and repairing streets. Business groups advocate the privatization of more of these activities to taxpaying, private companies. They claim that these services can be provided more efficiently and effectively if competition was permitted in contracting for services. Another segment of the private sector identifies business opportunities in financing, building, or operating large government projects, such as roads, bridges, airports, and waste-to-energy plants. In countries where nationalized industries exist, commercial pressure comes from business leaders who believe that the nationalized industries are mismanaged, slothful, and overtly underutilize existing assets. In such cases, denationalization (a particular form of privatization) is advocated. Denationalization presents the potential for innovation, whereas continued stagnation seems likely if nationalized industries remain protected from market forces. A lack of competition and protection of nationalized industries is viewed as counterproductive to innovation. State-owned enterprises or nationalized industries include a variety of enterprises such as manufacturing, mining, oil production, and transportation.

Finally, populist forces are believed to promote privatization based on widespread popular antipathy to the ideal of "big government." According to this viewpoint, government systems have become too institutionalized, too bureaucratized, too professionalized, and too protective of their own interest. Populist forces (common views of average citizens) advocate greater choice in public services, less reliance on cumbersome bureaucracies, and greater use of neighborhood, civic, church, and voluntary associations. Populist sentiment is believed to exist among citizens who are fearful of both big government and big business. These individuals find allies among advocates of family values and communitarians.

Other reasons to privatize are cited in the literature. Brinkerhoff^[3] contends that enhancing efficiency and effectiveness represents just one of a number of reasons to privatize. In addition to improving efficiency/effectiveness, public-private partnerships can also provide more integrated solutions to problems, improve outcomes for stakeholders, and promote a broader conception of the public good. More integrated solutions and improved outcomes are likely to arise when diverse actors cooperate with each other, with diverse actors free to present their own perspective. Expertise and relationships are also enhanced with greater cooperation. For example, multinational corporations and national government agencies often partner with local health agencies to learn more about decentralized/local health-care needs. In partnerships, local agencies often gain access to more capital, which, in turn, is used to address their problems. Creativity may emerge as diverse actors come together to address specific issues.

Partnerships can also create a broader understanding of the public good. Through such an understanding, sustainable benefits can be created. Social capital can be created in public partnerships, and this capital can be applied to other issues. For example, the U.S. Agency for International Development found that social capital could be developed and could facilitate continued relationships between donor and recipient organizations. This would foster support for long-term cooperation on issues of common concern.

DECLINE OF STATIST THINKING

It is no coincidence that the ascendancy of privatization thinking has coincided with a decline in "statist" ideology.^[4] Critics of countries characterized by "extreme statist experiments" (such as Cuba, Ethiopia, Mozambique, Vietnam, Laos, Cambodia, Burma, North Korea, and China) cite numerous reasons for the collapse of centrally planned societies. First, the assumption of self-centered behavior (looking out to maximize one's well being) is now recognized as applicable to both the public and private spheres. In statist societies, self-interest manifests itself in widespread corruption. Government officials use the pursuit of the common good and their ability to interpret the common good as a means to satisfy materialistic/individualistic desires. In the extreme, the selfless pursuit of common goals becomes a facade that masks individual self-interest. In contrast to classical economic thought, individual self-interest does not produce market competition/efficiency but allows public officials to extract personal rewards on the basis of their privileged government positions. Second, it is believed that "statism" fails to deal with the issue of incentives. Market incentives that imposed discipline on private sector managers and encouraged efficient production were simply not provided by the state. Third, building large-scale production units in urban areas of planned economies was detrimental to rural dwellers. Developing such units harmed those in rural areas and enriched only a small minority. Fourth, central planning neglected the question of quality. For example, Soviet oil fields were notorious for the amount of oil lost or wasted in production because Soviet managers were concerned with increasing output and not with making extraction less costly. Typically, managers in the Soviet Union were reluctant to develop new products for fear that production would temporarily lag. The private sector consumer-based market is more effective in promoting quality because profits are linked to a company's ability to attract customers. These customers are attracted on the basis of improved quality or reduced cost.^[5]

Inefficient state-run farms were commonly associated with statist countries. Analysts claim that state

entities consumed resources that would have better uses in other areas. For example, research has found that in developing countries where labor is abundant, small household farms are more cost-effective than large mechanized farms.^[6] In some nations such as Cuba, the cost of agricultural workers was found to be greater than the value of the sugar they produced. Empirical data indicate that the consequences of collectivization were not positive. In many developing nations, real per capita incomes were lower at the end of the 20th century than they were when the nations achieved independence from their colonial rulers.^[7]

Caustic criticism of the performance of statist regimes began to appear in the academic literature around the mid-1960s. By 1970, the Organization for Economic Cooperation and Development (OECD) published a study critical of state-centered import substitution industrialization (ISI) strategies that were prevalent in developing nations such as Argentina, Brazil, Mexico, India, Pakistan, the Philippines, and Taiwan. Soon after, the World Bank, in conjunction with the Inter-American Development Bank, published a study supporting the OECD's findings.

In 1983, the U.S. National Bureau of Economic Research (NBER) issued a report advocating export-oriented industrialization in contrast to import substitution characteristic of ISI-based regimes. According to the NBER, import substitution regimes were clearly less successful than regimes that focused on export-oriented industrialization. After adopting a market-based export model, some nations (particularly the Four Little Tigers or Dragons of East Asia: Hong Kong, Taiwan, Singapore, and South Korea) became models of efficiency, innovation, and prosperity. In per capita terms, these nations were the world's fastest growing in the latter decades of the 20th century.^[7] Few now dispute the NBER study's assertion that nations adopting export-based policies have performed better than nations adopting import substitution. The NBER study was so widely accepted that some began to call it the core of the neoclassical critique of statism.^[8]

As neoclassical economics regained acceptance, developing nations sought to forge partnerships with private sector companies in the developed world. In direct contrast to the prescriptions advanced in the ISI model (such as limiting imports of finished goods from developed countries and trade between poor countries), the neoclassical paradigm advocated trading between rich and poor nations.^[8] This model was embraced by economists who proclaimed that there was no need to articulate an economics for development because the market offered the best mechanism for poor countries to develop. Leaders of developing countries, however, still confronted numerous impediments to economic advancement.

CONSTRAINTS TO PARTNERING IN DEVELOPING COUNTRIES

An array of factors clearly influences the feasibility of creating partnerships in developing countries. Two factors that impinge on the ability to create partnerships relate to governance and institutional capacity.^[9] Governance in the form of laws, decrees, policies, actions, and regulations can encourage or discourage potential arrangements between public and private sector actors. Laws or decrees that inhibit profit-making, prohibit currency transfers, or limit market-based actions are likely to produce hostile environments for public-private partnerships. Governance factors considered hostile to partnerships include an absence of the rule of law principle, widespread corruption, and minimal access to policymakers. Legal impediments include overly burdensome administrative and financial requirements on potential partners. In the extreme, existing laws may outlaw the possibility of specific types of partnerships. Access to government decision makers and inefficient bureaucracies may be a source of concern. Finally, low levels of institutional capacity (witnessed in low levels of legitimacy and inexperience of major actors) can inhibit partnership creation.

Political risk also discourages investment. Five components of political risk have been identified in the literature. These risks include the danger of 1) violence or war, 2) currency restrictions, 3) contract interference, 4) expropriation, and 5) unfair regulatory environments.^[10] Violence from civil war, insurrection, and coups clearly has a deleterious impact on partnership investments. Violence often coincides with property destruction, theft, arson, and an inability to attract dependable workers. Developing countries such as Sri Lanka, Pakistan, India, Algeria, Liberia, Rwanda, and others have been plagued by large-scale violence.

Government policies restricting the ability of foreign investors to convert local currency into their home currency also constrain partnership development. Flows of funds from host states can be entirely blocked by local/host country restrictions. Such restrictive policies will severely reduce the likelihood of foreign investment. Investors find no compelling reason to risk their capital unless they can convert future profits to the currency of their home country. In some instances, foreign-exchange brokers are licensed by the host government to handle foreign exchange.

Major international events may lead to repudiation of contracts between parties. For example, the U.S.-imposed embargo against Iraq caused the cancellation of some contracts between the previous government of Iraq and some European companies. Fears of expropriation (the government confiscation of property) represent another risk. Notable examples of expropriation of assets include the takeover of foreign property

by the Castro regime following the Cuban revolution, the nationalization of foreign copper companies by the Chilean government, and the seizing of French assets by Tunisia following their independence in 1954. Finally, unfair regulatory treatment may inhibit investment. Unfair treatment includes government policies such as discriminatory tax treatment (taxes favoring the host's domestic firms), limits on access to materials needed for production, and limitations of access to local distribution systems. Private sector investors have an interest in clarifying these issues prior to making monetary commitments to enterprises in foreign nations. Whereas numerous constraints exist, there have been notable examples of successful public-private partnerships in developing nations.

EXAMPLES OF PUBLIC-PRIVATE PARTNERSHIPS IN DEVELOPING COUNTRIES

Innovative public-private partnerships have been created in both Africa and Asia. For example, in Africa, there is evidence that government officials have leveraged their niche as a center for tourism, particularly in regard to their notoriety in "big game" hunting.^[11] In various African public-private ventures, contractual arrangements are formed between a community or local institution and a private investor. These parties work together in establishing and/or operating tourism or hunting enterprises. Both the community/local institution and the private investor have rights and responsibilities under the contractual agreement. Two common forms of partnership include 1) establishment of tourism lodges and 2) leasing of hunting quotas. In the case of tourism lodges, communities either have an equity stake or receive payments from lodge operators. In the case of the sale of hunting quotas, bids are taken, and the income from the sales is either distributed to residents in the area where the hunting takes place or is used for community projects.

Both lodge construction and quota agreements have grown in popularity as rights over wildlife have devolved from the central government to the local community level. Numerous cash-starved communities in Africa view tourism as an opportunity for local economic development. Private investors have identified African tourism for its profit potential. This confluence of interests led to the creation of joint ventures between public sector officials and private investors. Specific examples of tourism joint ventures include the sale of hunting quotas in Zimbabwe, the lease of large blocks of land around game reserve in Botswana, and the tripartite agreements in South Africa between public sector conservation departments, private investors, and tribal authorities. The sale of rights to engage in trophy hunting (especially for the big five of lions,

leopards, elephants, rhinos, and buffaloes) is viewed as a potential source of revenue. Attention to sustainability and mutuality of interest is thought to be essential to the development of successful joint ventures. Written agreements and contract are important in developing the shared vision.

Another case of public-private partnership is the development of a partnership between government officials and private sector shippers to upgrade efficiency in the South Korean port city of Pusan.^[12] In the early 1990s, this was identified as a high priority of the South Korean government. The need for improved efficiency was evident to South Korean officials who were influenced by the fact that ports in general handled approximately 99.7% of Korea's trade, and the Pusan port handled about 90% of port trade. In 1998, the Pusan port was ranked as the fifth largest container port in the world.

South Korean officials focused on improving the flow of information, reducing the burden of government regulation, and shortening delays in unloading cargo. Prior to the 1990s, an estimated 50–150 documents were needed for delivering and unloading cargo. As a result of this and other factors, Pusan suffered from a perception of poor service. To improve the performance of the Pusan port, government officials concluded that better information was needed in regard to equipment availability (especially cranes and tractors for unloading), cargo losses/damages, and the availability of cargo pickup times. Each of these factors was dependent on accurate and timely flows of vital information.

To address the problem of poor service, the Korean government acquired state-of-the-art computer hardware and software between 1989 and 1990. This equipment was used in the creation of a new electronic information system termed electronic development interchange (EDI). Training of port workers for the system was instituted, and studies of the new system were conducted. In 1996, the new system was fully implemented by administrative fiat. Use of the new electronic system became mandatory among all private sector port users. Once it became clear that the Korean government had mandated participation, the private sector cooperated in the establishment of a public-private entity, the Korea Logistics Network Corporation (KL-Net). This company attracted investment from companies such as Hyundai Merchant Marine, Global Corporation, and others. By virtue of their investment, the private corporations became fully involved in KL-Net operations.

In this case, the government sector was a major initiator of the public-private partnership. The public sector invested in the creation of an EDI system, they used the coercive power of the state to guarantee use, and they received private sector contributions to run the system. From the perspective of improving port

performance, the partnership is viewed as a great success and a model for others in developing countries.^[12]

CONCLUSION

The repudiation of the centrally controlled economic system suggests that public-private partnerships will play an enhanced role in the economies of developing nations. These partnerships can be created as a consequence of state intervention (such as the case with the Pusan port) or more localized decision making such as the case of tourism in Africa. Whereas centralized economies such as those found in the former Soviet Union and Eastern Europe have been renounced, it is also doubtful that the 19th century style capitalism can be reintroduced. Given these parameters, it is likely that public and private sector officials will seek out cooperative arrangements as the mutuality of benefits becomes evident.

Punctuated Equilibrium

Scott E. Robinson

*Department of Political Science and Public Affairs, University of Texas-Dallas,
Richardson, Texas, U.S.A.*

INTRODUCTION

Punctuated equilibrium theory has become a prominent tool for explaining policy change processes. At the most basic level, punctuated equilibrium theory is an account of policy change that predicts long-term policy equilibria that are infrequently, but dramatically, interrupted by periods of large change. The origins of punctuated equilibrium theory in the disputes between incremental and non-incremental theories of budgetary change are reviewed in this article. Contemporary punctuated equilibrium theory and some of the recent trends in the research into this policy phenomenon are also discussed in this article.

Recent research on public policy has shifted its attention from studies of cross-sectional variation in policy adoption to temporal variation. Instead of studying, say, why some states have adopted high-stakes tests while other states have not, temporal policy change researchers have asked why states have adopted policies at some times rather than others. Interest in the temporal dynamics of policy adoption in fact go decades back, but the recent resurgence of interest in the temporal dimensions of policy changes are, in part, because of the emergence of the punctuated equilibrium theory of policy change in the 1990s.

In this article, I will trace the historical roots of the punctuated equilibrium model of policy change, lay out the basic theoretical propositions of the punctuated equilibrium model, and consider the recent directions in research on punctuated equilibrium models of policy change.

HISTORICAL ROOTS OF PUNCTUATED EQUILIBRIUM

Incrementalism

The scholar most responsible for bringing attention to questions of policy change was Charles Lindblum.^[1] In his famous article “The Science of Muddling Through,” he analyzed the tendencies for slow change in administrative and policymaking groups. He argued that the slow change was a product of three pressures on policymakers. First, the policymakers had to seek consensus on any policy change—particularly in the

American government, the focus of Lindblum’s article. Second, the policymakers had very little information about potential large changes. The larger the change, in fact, the less reliable the information policymakers likely have to consider for the implications of the change. Third, policy change tends to involve very high stakes. If a large mistake is made, it may be difficult to reverse the decision.

Lindblum’s conclusion was that incrementalism dominates the policymaking process. Slow, considered, and politically non-controversial policy changes are much more likely, Lindblum argued, than large, abrupt, and politically controversial policy changes. This approach was applied most prominently to the study of federal budgeting.^[2] In the adaptation of incrementalism to federal budgeting, Wildavsky emphasized the need for consensus as a source of budgetary instrumentalism. To avoid opening up old political struggles, Wildavsky argued that politicians would use previous budgets as a baseline and only modify budgets slowly year-to-year. The result was a political consensus on an incrementally changing budgetary process, Wildavsky contended.

Non-Incrementalism

While the incrementalist school of policy change was popular from the time of Lindblum’s seminal article, many policy adoption scholars disagree that incrementalism could fully capture the dynamism inherent in policy change. Notably, Schulman^[3] published a famous critique of incrementalism that attacked Lindblum’s theory using counterexample. Convincingly, Schulman argued that an incremental theory could not account for many important policy areas where one could not incrementally build up a program. While one may be able to incrementally start a social welfare program (say by having pilot programs with steadily increasing scope), one could not, Schulman pointed out, build a space program incrementally. The space program was one where there had to be an initially large, non-incremental investment for the program to ever start. Schulman argued that policies that are essentially indivisible (one cannot, for example, have 12% of the space program—you pretty much have one or do not have one) will be characterized by non-incremental policymaking.

The Schulman critique of incrementalism was characteristic of the dispute between supporters of the incrementalist and non-incrementalist perspectives. The supporters of incrementalism would contend that they identified a tendency in the political process. The detractors would point to counterexamples to illustrate the non-universality of the theory. Along with conceptual ambiguities in what constituted “incremental” change, the debate became bogged down and researchers lost interest in the question.^[4]

THE EMERGENCE OF THE PUNCTUATED EQUILIBRIUM THEORY

The basic conflict between incrementalist and non-incrementalist theories was easy to identify. Incrementalists were right in that the predominant mode of policy change was slow and deliberate. However, non-incrementalists were correct in that many (most even) important policy changes were non-incremental. This left incremental theory incapable of explaining many important policies. What was needed was a theory that accounted for the common experiences with incrementalism while still allowing for occasional non-incremental policy change.

The solution to the problem came in the form of a book, written by Baumgartner and Jones, *Agendas and Instability in American Politics*.^[5] In their study of agenda setting in American politics, Baumgartner and Jones had seen a common pattern emerge. Attention to policy issues seemed to change slowly most of the time. Occasionally, however, there would be dramatic episodes of large change.

The best example of this was the attention to issues surrounding nuclear power. Attention to nuclear power issues changed slowly over time through most of the 20th century. One notable exception to this pattern of incremental evolution of attention was the Three Mile Island incident. Immediately following the incident, attention to nuclear power issues shot up. This was clearly an episode of non-incremental change in attention. Baumgartner and Jones identified similar non-incremental shifts in attention in such issues as pesticide controls.

To explain the mixed pattern they observed, Baumgartner and Jones borrowed a popular model of evolutionary change proposed by Eldredge and Gould.^[6] In punctuated equilibrium models of evolution, one does not expect to see gradual change over time in the fossil record. Instead, punctuated equilibria suggested that one should find long periods of stability (especially in the phenotypic characteristics of species) rarely interrupted by periods of abrupt change. These periods of abrupt change were called “punctuations,” while the periods of stability were seen as “equilibria.”

Baumgartner and Jones adapted this approach for studying change processes. They argued that agenda setting processes produced mechanisms of negative and positive feedback. When the mechanisms of negative feedback are dominant, as is the case in most situations, institutions militate against large changes in attention and policy. In these periods, policymaking proceeds through the traditional policy subsystems rather than broad public participation. The denial of tools to expand the conflict makes it difficult for actors to substantially change the status quo.

However, events can create mechanisms of positive rather than negative feedback. The example of Three Mile Island was again instructive. The public nature of the event expanded the conflict to include almost everyone in the country. The policy subsystem was broken wide open by the broad attention generated by the Three Mile Island event. This set in motion a series of positive feedback loops. The more people were paying attention to the issue, the more media and political attention was brought to the policy area. The more media and political attention, the more stable the public attention. The broad attention fed itself. More and more people were aware of nuclear power issues. Soon it became one of the leading issues of the day, not long removed from its previous state of agenda obscurity.

The combination of positive and negative feedback mechanisms in the policymaking system, Baumgartner and Jones argued, created the characteristic pattern of punctuated equilibrium theory—long periods of stasis punctuated with short periods of abrupt, large change. This was the pattern that had caused so many disputes between the incrementalists and the non-incrementalists. The incrementalists could point to the long periods of stasis as evidence of their approach. The non-incrementalists could point to the episodes of punctuation as evidence of the limitations of the incremental approach. Punctuated equilibrium promised the possibility of integrating the incrementalist theories (to explain negative feedback processes) and the non-incremental theories (to explain the positive feedback processes) in one encompassing theory.

ADVANCES IN PUNCTUATED EQUILIBRIUM THEORY

The first step in proving the importance of punctuated equilibrium theory was to demonstrate the pervasiveness and importance of punctuated equilibrium processes. While the original Baumgartner and Jones text^[5] had identified some examples of punctuated equilibria, it had not demonstrated how common these processes were. The disputes between incrementalists and non-incrementalists had suggested that the pattern may be common—even universal—but a general

demonstration was needed. Given the centrality of budgeting to the dispute between incrementalists and non-incrementalists, it was only natural to start by looking at the distribution of budgetary change.

True, Jones, and Baumgartner^[7] provided a demonstration that punctuated equilibrium described the actual distribution of U.S. federal budgetary changes better than did traditional incremental or rational choice explanations. What they found when they looked at the distribution of federal budget appropriations was a characteristically leptokurtic distribution—i.e., a distribution characterized by a large number of observations at its peak (in this case, around a slow growth value), a large number of observations of large change (in both the positive and negative direction), and a smaller than expected number of moderate changes. The distribution of federal budget appropriations indicated that small and large changes were easier to make than would have been expected, while moderate change was harder than expected. This is exactly the descriptive prediction of the punctuated equilibrium theory. Long periods of stasis would produce a large number of observations of small change. The rare, but dramatic, punctuations would show up as an unexpectedly large number of large changes. These unexpected observations (unexpectedly common small and large changes) would come at the cost of reducing the frequency of moderate changes. The analysis of U.S. federal appropriations budget convincingly demonstrated the existence of punctuated equilibrium.

Recent work in the punctuated equilibrium tradition has moved from the demonstration of the existence of punctuated equilibria to testing of the causes of punctuated equilibria. Jones, Sulkin, and Larsen^[8] showed that punctuated equilibrium theory could provide the basis for predictive hypothesis testing. They found that the stages of the policymaking process grew increasingly “punctuated” from agenda setting to policy budgeting. The degree of punctuation seemed to increase as one moved from settings like popular media and popular elections to highly institutionalized setting like legislative budgeting. The authors contended that this pattern indicated an increase in institutional friction as one moved through the policy process. Other authors found that factors such as the nature of the policy activity^[9] or bureaucratization of the policymaking institutions also affected the degree of punctuation.^[10] This research reassured scholars that punctuated equilibrium was a theory with predictive power and a subject worthy of continued investigation.

THE FUTURE OF PUNCTUATED EQUILIBRIUM RESEARCH

The future looks bright for research into punctuated equilibrium models of policy change. The recent

attention to hypothesis testing has opened up new avenues of research and theory development.

The most obvious recent development is the broadening of the scope of punctuated equilibrium research. While previous research had been largely limited to U.S. federal data^[7,8] (with some forays into local budgets,^[9,10]) recent research increasingly deals with policymaking institutions in other areas. Punctuated equilibrium patterns at other levels of policymaking—including international comparisons^[11] and comparisons between states in the U.S. system—have been investigated in a recent work.^[12] Expanding the research into new institutional contexts has allowed for the investigation of institutional contributions to punctuated equilibrium in ways that the federal budgeting studies have not been able. International studies have been able to investigate the impact of parliamentary systems of punctuated equilibrium,^[11] while the studies in U.S. states have allowed investigators to consider the role of federal specialization on punctuated policymaking.^[12]

CONCLUSIONS

More work remains to be done to better understand punctuated equilibrium theory. First, work remains to uncover the causes of punctuated equilibrium. A great amount of work is still to be done to help us understand why some policy processes seem more prone to punctuated equilibria than other processes. Suggestions like “institutional friction”^[8] help us pin down the exact causes—though this is only a beginning. There are also methodological challenges ahead. Most of the studies have heretofore compared samples of policy outputs rather than individual policy outputs. This limits research substantially because the comparisons tend, then, to be discrete and univariate. Recent work has sought to provide a system to study punctuated policy processes at the individual input unit of analysis, but these are only the first steps at multivariate analyses.^[13]

Punctuated equilibrium theory has proven to be a useful way to resolve the disputes between incremental and non-incremental theory. While it is still a new theory, the existing work leads to the suggestion that it is a promising tool in understanding policy change process.

Q Methodology

Dan Durning

Carl Vinson Institute of Government, University of Georgia, Athens, Georgia, U.S.A.

INTRODUCTION

Q methodology is used for the systematic study of subjectivity; that is, it provides a way to investigate empirically how an individual, separately or as part of a group, thinks about a topic or issue of interest. As Brown expressed it, Q methodology “examines the world from the internal standpoint of the individual being studied” (on page 1 of Ref.^[1]).

The name Q methodology is intended to differentiate it from the “R” methods of conventional statistics that typically measure variables such as the characteristics, attitudes, or behaviors of populations (or their samples) and seek to determine the relationships among those variables. Although Q methodology makes use of factor analysis, one of the more sophisticated R methods, it has more in common with qualitative methodologies and their quest to understand humans and their behavior in their full complexity.

This article introduces the origins of Q methodology, describes its developments, and illustrates how it has been used in public administration and public policy research. After that, the article explains both Q-sort technique and its underlying framework. It concludes by suggesting that Q methodology is attractive to some researchers for the types of insights it provides and to other researchers for philosophical reasons.

HISTORY AND DEVELOPMENT OF Q METHODOLOGY

The origins of Q methodology can be traced to a letter written in 1935 by Stephenson to the editor of *Nature*, a British journal, which suggested the value of “inverting” the matrix of observations and variables in conventional factor analysis to correlate persons rather than tests (on pages 9–11 of Ref.^[1]). He proposed that researchers begin with a population of tests (“or essays, pictures, traits or other measurable material”) that would be “measured or scaled” by a set of individuals. The intercorrelations of the measures would then be subject to conventional factor analysis. In this correlation matrix, the observations would be the tests (or other measures), and the variables would be the people who completed them. Thus, factor analysis of

this inverted matrix would identify variables (that is, persons) with similar responses to the tests or other measures.

Stephenson’s 1935 letter and subsequent articles made it clear that Q methodology had two main elements. The first, highlighted in the letter, was the technique of “inverted factor analysis.” The second element was present, but less developed, in the 1935 letter: the nature of the observations—the tests or measures submitted to the individuals for them to complete. According to Stephenson, these tests or measures differ from those used in R methodology (on page 15 of Ref.^[2]). In fact, he emphasized that data collected for R method analysis cannot be inverted for use in Q methodology. Stephenson’s later work on Q methodology, which lasted until his death in 1989, linked the measures to be used in Q methodology to communication and other theories.

At the time Stephenson proposed the Q methodology innovation, he had completed two doctorates, the first in physics at Durham University (1926) and the second in psychology at the University of London (1929). As a psychology doctoral student, he was the last graduate assistant of Charles Spearman, the inventor of factor analysis. In 1936, he was appointed Assistant Director of the Institute of Experimental Psychology at the University of Oxford, where he remained until 1948. That year he moved to take a position in the University of Chicago’s Psychology Department. In 1958, he became a faculty member at the University of Missouri’s School of Journalism, where he taught until he retired.

Stephenson’s definitive book on Q methodology, *The Study of Behavior: Q-Technique and Its Methodology*, was published in 1953. It set out systematically the theoretical foundations of Q methodology.^[2] Although Q methodology, as formulated by Stephenson, was ignored, even shunned, for decades in psychology, many of his students at Chicago, Missouri, and other universities found it to be a valuable research method, and some became the second generation of Q methodologists.^[3]

A leader among the second generation has been Steven R. Brown, professor of political science at Kent State University, who has both promulgated Q methodology tirelessly and contributed important new

insights into it as a tool for the study of subjectivity in the social sciences, especially political science. Brown's 1980 book, *Political Subjectivity: Application of Q Methodology in Political Science*, joined Stephenson's *Study of Behavior*, as an essential book on Q methodology for social scientists.

In recent years, several scholars have employed Q methodology in their public administration and public policy research and practice, and several how-to guides are available for them and others interested in carrying out Q methodology research [e.g., Refs.^[4–6]]. The utility of Q methodology can be seen in the following four examples of ways that Q methodology has been employed by researchers:

- *Investigating a major issue of interest in public administration:* Brewer et al. used Q methodology to understand better why people choose to work in the public sector.^[7]
- *Identifying the subjectivities of stakeholders in policy issues:* Steelman and Maguire are among several researchers who have employed Q methodology in recent years to clarify competing stakeholder perspectives on particular policy issues or broader issues areas.^[8] They focused on the values of stakeholders in forest policy.
- *Managing conflict over policy issues:* Some scholars have turned to Q methodology to help resolve controversial policy issues. For example, Focht used Q methodology to assist in formulating a strategy to manage conflict over the use of the Illinois River Watershed in Oklahoma.^[9]
- *Identifying policy alternatives for intractable problems:* Van Eeten showed how Q methodology was used to “recast intractable problems” so as to make them more amenable to solution. He described the efforts to determine the future policy for expanding Amsterdam's Schipol Airport.^[10]

For a summary of public administration and public policy research carried out with Q methodology, see Ref.^[5].

It should be noted that Stephenson's approach to Q methodology is not the only one. In fact, the dominant definition of Q methodology in psychology has, from its beginnings, portrayed it simply as “inverted factor analysis.” This view was promoted by Cyril Burt, a major presence in British psychology for decades (see Refs.^[1,2]). He maintained that Q technique could be carried out using the same data (from “objective” measures) collected for R studies. With that data, R factor analysis would identify correlated traits and, transposing the matrix, Q factor analysis would identify persons with related characteristics. Burt's definition of Q methodology is still found in many methodology books for psychologists and social scientists.

Q-SORT TECHNIQUE

The process of conducting a Q method study consists of three major elements: 1) constructing the measurement instrument (the Q sample) and selecting the persons to be asked to complete the measurement instrument (the P set); 2) administering the measurement instrument (Q sorting) and analyzing the completed instruments (the sorts) using factor analysis; and 3) understanding or interpreting the results of the factor analysis to identify the different subjectivities (structures of thought) about the issue or topic of interest among the individuals who completed the Q sorting.

The Q Sample and P Set

The starting point for creating the measure instrument for a Q methodological study is to identify the “subjective communicability” about the topic of interest.^[11] For example, to research individual subjectivity on a topic such as illegal immigration, the researcher identifies what is being said or written about that topic. The body of written and spoken communication on illegal immigration makes up its “concourse.”^[12] This communication appears in newspaper articles, journals, websites, blogs, and television talk shows—wherever people have an opportunity to express their opinions. It can also be found by interviewing people who have different perspectives on the issue and by listening to conversations that occur every day in life.

When collecting statements of individual opinions, beliefs, and feelings about the topic, the researcher does not edit the statements for clarity nor assume that each statement has one specific meaning that can be determined. The researcher's goal is to collect enough communications in their natural form so that all perspectives are heard and included.

From the tens, hundreds, or thousands of statements on a topic, the researcher selects a Q sample, a set of statements that are a good representation of the diversity of the concourse. The selection of representative statements is not done randomly but is a purposeful activity by the researcher to ensure that the full range of subjectivity is included in the Q sample. Often, the researcher will use an experimental design to assist in selecting the statements (see pages 186–191 of Refs.^[1,10]).

While creating the Q sort, the researcher can also select the individuals who will be asked to participate in the study. These individuals (the P set) may be selected for any number of reasons. For example, the researcher may be interested in how members of a city council view an important policy issue and will ask each member to take part in the research. Or the researcher may want to know the views of social

service professionals on the issue and will select as research participants several of them who will likely have a diversity of views.

Because Q methodology is an intensive methodology, the P set will be small. In fact, Q methodology studies can be carried out with one individual, who sorts Q sample statements from different viewpoints (or “conditions of instruction”). Alternatively, the P set might reach a hundred or more; however, most will include much fewer than a hundred persons. Whatever be the number, the purpose of Q methodology is to identify different perspectives on a topic; it does not provide information on the distribution of those perspectives among P populations.

Administering and Analyzing Q Sorts

The Q sample is the measurement instrument administered to the P set through Q sorting. The mechanics of Q sorting include a Q-sort deck, instructions for sorting statements from a particular perspective and along a specified scale, and interaction with the individual completing the sort to understand better why statements were placed as they were on the continuum.

The Q-sort deck consists of the statements from the Q sample typed one to a card and numbered randomly. The individual is provided with the deck and asked to place a specified number of statements at each point on the scale (see Fig. 1) in a way that reflects the individual's views on the topic being researched. Typically, the statements are sorted in a quasinormal distribution. The forced sort makes sure that the person will place each statement in relation to all of the other statements. During the sorting process and after, the researcher can ask the participant to explain the rationale for placing certain statements at the end points on the scale (e.g., +4, -4). This conversation assists with the researcher's efforts to understand and interpret factors.

After the Q sorting is completed, the sorts are inter-correlated and the correlation matrix is factor analyzed. The factor analysis includes rotation, either through standard procedures or by hand rotation using the judgment of the researcher. The result is the identification of factors on which people with similar views have significant loadings. These factors represent different perspectives (subjectivities) on the topic being researched.

Understanding/Interpreting the Factors

The perspective of each factor is made clear by calculating its weighted average Q sort. The average is weighted so that the views of the persons with the highest factor scores have the greatest influence on the average sort. With these weighted average sorts for each factor, it is possible to determine how each factor ranked (or scored) each statement.

Examining the average sorts for each of the factors, the researcher seeks to understand the viewpoint of each factor. The researcher pays particular attention to the statements put at the end points of the continuum (e.g., +4 and -4). Also, the researcher identifies statements for which the scores of different factors diverge significantly and those for which they have similar positions. Free software (PQ Method) is available to assist with all aspects of the analysis of completed Q sorts and the interpretation of the identified factors.

The researcher will not know in advance how many factors (perspectives) will be identified or what the nature of the factors will be. The subjectivities that emerge from the sorts have not been constrained nor determined a priori by the researcher.

METHODOLOGICAL FRAMEWORK

In creating Q methodology, Stephenson's main innovation was not using factor analysis to “measure persons” instead of tests, but rather his stance that inner experience (individual subjectivity) could be measured and analyzed by the same scientific methods used to measure externally observed behavior.^[2] He insisted that the statistical procedures that correlate traits across populations could be employed to gain insight into the thoughts, opinions, and feelings of one individual. Stephenson maintained that subjectivity (thoughts, attitudes, and feelings) is behavior as real as any physical act, and he devised Q technique to make subjectivity manifest and to analyze it.

The evolution of Q methodology from its focus on single-case psychological studies to multi-individual research in other disciplines has accelerated in the past 25 yr. Part of the acceleration came as a result of further development of the theory behind the construction of measures to be used in Q-sort technique. In the 1970s, Stephenson linked these measures to his

Fig. 1 Example of Q sorting scale and distribution.

concourse theory, which suggests that the universe of subjectivities on a particular issue or topic can be found in the flow of communication about it.^[12]

Just as R methodology rests on a foundation of assumptions about the nature of the knowledge, Q methodology has its own foundation. R methodology is employed to provide an objective analysis of an issue or topic. It is founded on logical positivism, in which the researcher is an outside observer with a privileged (maybe superior) vantage point from which the researcher can observe without affecting the subjects. The researcher seeks to obtain—or approach as closely as possible—objective truth. In contrast, Q methodology is closely related to the postpositivist perspective that rejects the possibility of observer objectivity and denies that the observer occupies a privileged position.^[13] It posits the existence of multiple realities and seeks to measure them. Thus, Q methodology is consistent with phenomenological, hermeneutic, and quantum theories.^[14,15]

Reflecting the Q methodology framework, the work of the researcher in a Q methodology study is visible and explicit: The researcher purposefully selects the Q sample and P set, may hand rotate the factor analysis using insights gathered during the research process, and interprets the factors to understand the different subjectivities. However, the purpose of the involvement is simply to enable individuals to express their subjectivities freely and to assist the researcher to understand those subjectivities.

CONCLUSION

In the past 15 yr, Q methodology has been utilized by researchers in growing number of fields and disciplines, including public administration and public policy.^[5] Part of Q methodology's attraction is that it provides information not accessible through R methods. Some researchers find it attractive because of its philosophical stance, including its postpositivist foundation, and have suggested that Q methodology should be taught as a research method in policy schools.^[16]

At present, Q methodology does not have a place in most public administration and public policy methods courses. However, its increasing use by public administration and policy researchers shows its potential contributions to both disciplines.

Quantitative Decision Making: Benefit–Cost Analysis

Jay P. Hamilton

*Department of Public Management, John Jay College of Criminal Justice,
New York, New York, U.S.A.*

INTRODUCTION

Benefit–cost analysis (or cost–benefit analysis) is a quantitative decision-making tool, used by policy makers and public administrators to assess the efficiency of public policy. Benefit–cost analysis uses a single metric to determine the net benefits of a policy or project for a well-defined group of people. The policy’s consequences are measured in currency units. For the United States, the dollar value of all benefits accruing to all people in the well-defined group is compared to the dollar value of all costs accruing to all people in the well-defined group. If the benefits exceed the costs (positive net benefits), then the policy maker or public administrator can use the analysis to justify proceeding with the project. If the policy maker rejects implementation of a project with positive net benefits or proceeds with a project that fails to produce positive net benefits, then the decision maker must justify their decision in light of the empirical evidence. Benefit–cost analysis helps decision makers find an optimal solution when deciding between different projects in which there are several proposed options. In this situation, benefit–cost analysis informs the decision maker about which projects return the greatest net benefits or the greatest rate of return.

OVERVIEW

Benefit–cost analysis has been applied to many areas of public decision making. Major public works such as dams, levees, and roadways are frequently subject to benefit–cost analysis prior to construction.^[1] Benefit–cost analysis has been applied to various health-care policy discussions, such as drug abuse prevention programs.^[2] Social regulations designed to protect the environment and worker safety are commonly, but not always, subject to benefit–cost analysis.^[3] In the field of criminal justice, benefit–cost analysis has been applied to evaluate the efficiency of early childhood intervention programs, such as preschool for the disadvantaged, in preventing future crime.^[4] Economic regulations such as minimum wages and tariffs are also subjects of benefit–cost analysis.^[5] In principle, any policy or public decision can be subject to benefit–cost analysis.

Controversy surrounds benefit–cost analysis in its theoretical underpinnings and in its application. Although benefit–cost analysis appears to be objective, its theoretical foundations are based on at least two value judgments.^[6] First, society’s welfare is derived from individual preferences. Thus, benefit–cost analysis is the sum of the net benefits received by all individuals affected by the policy or project. Second, the importance of individuals’ preferences is not equal, because money is used as the metric of comparison. Individuals with greater wealth have a greater influence on the valuation of benefits and costs. In practice, benefit–cost analysis can be reweighed to compensate for the wealth bias, but the reweighing depends on a value judgment made by the analyst or the decision maker. Those who support benefit–cost analysis argue that all public decision making will involve some implicit or explicit value judgments, but a thoroughly documented benefit–cost analysis will highlight the sensitivity of any value judgments and will produce a quantified report with details that can be scrutinized.

The controversies of benefit–cost analysis application are numerous and varied. Five categories of concerns are discussed here, after a brief history of the development of benefit–cost analysis. The first area of controversy is defining the questions the analysis will help answer. The decision maker and analyst must agree on the relevant sphere of influence of the policy, as well as the depth to which the analyst will look for consequences of the policy. Once consequences are identified, the second area of controversy is the valuation of those consequences. The dollar estimation of intangible values necessarily involves many methodological choices for the analyst. Third, the analyst must take into consideration the time frame of the consequences of the policy, which implies a choice of discount rate for future benefits and costs. Fourth, the analysis must deal with issues of uncertainty. Last, the decision maker must consider the impact of the distribution of benefits and costs across different segments of society. While the principle of benefit–cost analysis is simple, the application is often intricate. All practitioners of benefit–cost analysis agree that final reports should clearly state assumptions and should contain sensitivity testing of those assumptions.

THE ORIGINS OF BENEFIT–COST ANALYSIS

The origin of cost–benefit analysis is widely attributed to the United States Army Corps of Engineers, which took the first steps toward formulating a consistent benefit–cost analysis methodology in the 1930s. Charged with the task of evaluating various improvements in the nation’s waterways, the Corps generated reports estimating the costs required for each project. The Flood Control Act of 1936 authorized the Department of Agriculture to estimate projects’ benefits “to whomever they accrue” and compare these benefits to estimates of the projects’ costs. After 1936, the history of benefit–cost analysis can be divided into two categories: 1) the search for theoretical foundations by welfare economists and 2) improvements in the application of benefit–cost analysis.

The study of welfare economics has long been dominated by the concept of “Pareto Optimality” that states: A distribution of outcomes/benefits is deemed efficient if no individual or group can be made better off without making even one person worse off. The Pareto Optimality criterion is relatively uncontroversial but also largely inapplicable to public decision making, because nearly every public decision creates winners and losers. The Pareto criterion cannot justify the use of benefit–cost analysis. In 1939, Hicks and Kaldor, working independently, crafted a “modification” to the Pareto criterion, which became known as the Kaldor–Hicks compensation criterion.^[7,8] Under this rubric, a policy will improve public welfare, if the gains to the winners are large enough such that the winners can compensate the losers and still be better off than before the policy. The Kaldor–Hicks compensation criterion is often considered a utilitarian approach to policy making. Critics of the Kaldor–Hicks compensation criterion are quick to point out that compensation does not need to be paid, and, thus, a policy that passes the test may give all the gains to one person and create many losers.^[9]

To facilitate the practice of benefit–cost analysis, agencies using this decision-making tool began publishing guidelines in the late 1930s. In the 1950s, the Rand Corporation also refined the analysis process when drafting rules to guide decision makers in selecting military objectives.^[10] Around the same time, health economists began using cost-of-illness as well as cost–benefit analyses to evaluate various health policies. Over the 1960s and 1970s, the use of benefit–cost analysis spread throughout other U.S. government agencies and overseas to Great Britain, the Organization for Economic Co-operation and Development, United Nations Industrial Development Organization, and the World Bank. In the 1980s and 1990s, the use of benefit–cost analysis spread to environmental, safety, and health regulations. Although most presidential

administrations advocate the use of benefit–cost analysis, not all legislation has embraced this decision-making tool. Most notably, the U.S. Clean Air Act of 1970 makes no mention of the need to evaluate the costs of regulations drafted in support of the act. The courts have upheld the practice of ignoring the costs of clean air regulations. More recently, the Job Creation and Wage Enhancement Act (H.R. 9, 1995), which passed the House of Representatives but failed to reach the Senate floor in the 104th Congress, mandated the use of benefit–cost analysis in all new regulations issued by the federal government.

DEFINING THE ANALYSIS

The first step in conducting a benefit–cost analysis is defining the decision the analysis will evaluate. Sometimes the question at hand is simple, such as whether or not to dredge a harbor. Other decisions are more complex, creating an array of options for the decision maker to choose from. For example, the decision to adopt a new safety regulation for cars may involve deciding how quickly to implement the new safety rule. Should the new device be phased in or be adopted immediately? Immediate adoption may be costly compared to a gradual introduction; if the benefits mostly accrue far into the future, then a gradual approach would be appropriate. The analyst should help the decision maker determine how quickly to implement the new regulations. As a second example, consider the decision to build a flood control levee. Benefit–cost analysis should not simply give an up or down answer; the final report should present a range of conclusions based on different heights for the levee. The more complicated the set of questions the benefit–cost analysis is called upon to answer, the more complicated the final report.

Once the appropriate project is identified, the analyst must construct a list of all the consequences of the decision. This includes a somewhat arbitrary decision about the relevant sphere of influence for the decision maker. Does the decision maker mandate the inclusion of benefits and costs that accrue only to their constituency? Or is there a greater sense of public? For example, a regulation in the United States reducing the emission of sulfur oxides from coal-burning power plants will reduce the incidence of acid rain in Canada. The decision maker must decide if the benefits to Canadians should be included. A good benefit–cost report would compare both options so that the policy maker can make the final decision. But as the number of such issues increases, so will the complexity of the final report. An intractably complicated report containing a myriad of conclusions defeats the lucidity of benefit–cost analysis that makes this quantitative tool so attractive. The analyst should

open this discovery phase to the public and seek a wide range of opinions about the sphere of influence and the potentially relevant consequences.

VALUATION

The analyst must attempt to assign a dollar value to all costs and benefits for each consequence of the policy; if the analyst is unable to do this, then the exceptions must be clearly stated. Many costs and benefits will be easily estimated from existing market data. The direct cost of constructing a dam is readily estimated from previous dam constructions, as are the benefits from power generation, irrigation, or flood control. However, many benefits and costs are not easy to estimate. In the case of dam construction, examples of negative consequences that are difficult to assign dollar values include habitat loss for native animal and plant species, addition of greenhouse gases from rotting vegetation in the reservoir, and lost recreational value. Among the intangible benefits where value is hard to assess are habitat saved from flooding, lives saved, and increased recreational value on the reservoir. Valuation estimation of non-market benefits and costs often occupies much of the analyst's time and creates much of the strongest debate.

There are many established techniques used to value non-market benefits and costs; all of them are anthropocentric, meaning that only those benefits and costs that accrue to humans are included in benefit–cost analysis. One such technique, Hedonic valuation, decomposes the market to extrapolate values for non-market goods. For example, the external costs of industrial pollution can be estimated by the reduction in residential land values surrounding the polluter. Therefore, an environmental regulation that reduces pollution will have a benefit of increased property value. There are other markets that can be dissected by Hedonic valuation. Analysts can examine differences in pay based on occupational hazards, to determine the value of safe working conditions. Another popular application of Hedonic valuation is the travel cost method, where a natural amenity with free access is valued by the money people spend to reach the amenity.

Some intangible values can be inferred from jury awards and political decrees. If benefit–cost analysis is used for a policy that saves lives or potentially costs lives, then the value of a human life is a critical item that must be valued carefully. The analyst may choose to estimate the value of human life by considering the damages awarded in wrongful death lawsuits. In practice, this involves estimating the future earnings of the deceased. The value of a person is equivalent to their value in the labor market. Also known as the human capital approach, this method of valuation

suffers from labor market imperfections such as diminished wages for women and minorities.^[11] The body politic may also provide financial compensation for intangible losses such as those that occur when a person is wrongfully imprisoned.

The benefits of a policy can be estimated by using the private expenditures made by individuals in their efforts to avoid or diminish a problem that will be solved by the policy. This approach is commonly referred to as the aversion-cost approach. For example, a private citizen who lives next to a freeway may construct a large wall to diminish freeway noise pollution. When considering new freeway projects, the cost of noise pollution may be estimated by extrapolating the costs private citizens pay to reduce the noise.

Another approach to evaluating benefits is contingent valuation. This method utilizes a scientific survey that asks people to place a value on policy issues. Contingent valuation should attempt to frame the questions in a meaningful and non-biased manner, so that respondents will answer honestly. Many contingent valuation surveys will propose simple yes or no questions, such as, “is preserving forest X worth an additional cost of \$75 per property per year in property taxes.” Different respondents are given different amounts. The analyst then uses statistical analysis to estimate the average willingness to pay for the potential benefit. The distribution of wealth will influence the estimates produced by contingent valuation surveys, because respondents' willingness to pay for a policy is a function of income and wealth.

Consider a policy designed to reduce crime. The analyst must estimate the intangible costs of crime imposed directly on victims and indirectly through fear created in the general population. This is necessary because the elimination of those costs is the main benefit of crime prevention. There are several methodological approaches the analyst can use. The analyst may choose the Hedonic valuation method to statistically isolate the component of property values attributable to ambient crime rates. However, the analyst must be careful to control for other factors that influence property rates, such as the prevalence of low-wage incomes, proximity to polluters, disappointing school districts, etc. Not all of these data will be easy to obtain. The analyst may choose to extrapolate the costs of crime from jury awards connected to past crime. But, this methodology takes data from a jury award given to a specific victim and applies the data to the valuation of crimes prevented for unknown persons. Because of the face-to-face nature of jury trials, they are likely to award penalties far in excess of what society would be willing to pay to prevent the same crime. The analyst may choose to apply an aversion-cost approach. The analyst could estimate the benefits of increased law enforcement by calculating

Table 1 Present value of a \$1,000,000 future value

Years into the future	Discount rate						
	00.0%	00.5%	01.0%	05.0%	10.0%	15.0%	25.0%
1	\$1,000,000	\$995,025	\$990,099	\$952,381	\$909,091	\$869,565	\$800,000
10	\$1,000,000	\$951,348	\$905,287	\$613,913	\$385,543	\$247,185	\$107,374
20	\$1,000,000	\$905,063	\$819,544	\$376,889	\$148,644	\$61,100	\$11,529
50	\$1,000,000	\$779,286	\$608,039	\$87,204	\$8519	\$923	\$14
75	\$1,000,000	\$687,932	\$474,129	\$25,752	\$786	\$28	\$0
100	\$1,000,000	\$607,287	\$369,711	\$7604	\$73	\$1	\$0

the money spent on private security measures such as barred windows, locks, alarms, gun sales, and private security services. Finally, contingent valuation surveys may be the best way to estimate society's willingness to pay for the prevention of certain crimes, but surveys are costly and time consuming.

DISCOUNTING FUTURE BENEFITS AND COSTS

There are several aspects of benefit–cost analysis of special concern to the policy maker. Many of the benefits and costs of decisions made today will have an impact several years in the future. As a general rule, people do not value the future as much as they value the present. Therefore, any future benefits or costs should not be considered the same as current costs and benefits. Future costs and benefits are discounted. The rate at which future benefits and costs are discounted is a question of considerable debate. Future benefits and costs are discounted according to the following formula:

$$PV = FV/(1 + r)^t,$$

where

PV = the present or discounted value to be included in the sum of benefits and costs,

FV = the estimated future value of the benefit or cost,

r = the discount rate per time period, and

t = the number of time periods into the future until the benefit is realized.

The future values should be estimated in current dollars to avoid inflation complications. As t increases, the impact of future benefits and costs on present value is reduced because of the compounding nature of the formula. Table 1 demonstrates the impact of discounting in biasing benefit–cost analysis against preferences of individuals in the future. As we go down any column with a positive discount rate, we see that the present value of a one-million-dollar future value gets smaller the farther we go into the future.

Many benefit–cost predictions hinge on the value of the discount rate, r . For example, a program to store nuclear waste will have large costs today, but the benefits will be felt for thousands of years. If a low value of r is chosen, then the program has a better chance of passing the benefit–cost test than if a high value is chosen. A good report will present a range of present values that use several different discount rates. Table 1 demonstrates the powerful impact of the choice of discount rate. As we go across any row, the discount rate increases, and the present value for a one-million-dollar future value gets smaller.

Some people argue that the discount rate should be set at the prevailing interest rate, because society can capture the benefits of some future consequence today, by taking out a loan with the future benefit as the eventual amount of the loan repayment including interest charges. However, such a practice makes the analysis subject to the whims of financial markets that may have little relationship to society's time preference. For example, few financial instruments extend beyond a 30-yr maturity, but many public works will last much longer. However, interest rates may be the correct choice for costs, because the present value represents the amount of money that would need to be set aside and invested today so that compound interest would provide enough funding in the future. Some analysts prefer to conduct an internal rate of return analysis, where the objective is to find the discount rate, where the sum of the present value of benefits exactly equals the sum of the present value of costs, and, thus, the decision maker simply decides if the resulting discount rate accurately reflects society's rate of time preference. Some people argue that the discount rate should be set to zero, making future benefits and costs equivalent to today's benefits and costs.

UNCERTAINTY

Many of the consequences resulting from public decisions are not certain. To the extent that benefits and

costs are uncertain, quantitative estimates of those benefits and costs must be adjusted to incorporate the uncertainty. Analysts commonly estimate the riskiness of the consequences. The analyst will, using the best information available, assign a probability to every possible outcome. If a policy is estimated to have two potential outcomes, say a one-million-dollar net benefit occurring with a 10% chance or a zero net benefit occurring with a 90% chance, it would be tempting to simply say the expected net benefit is \$100,000, the mathematical expectation. However, people are generally risk averse, meaning they would rather take a certain net benefit less than \$100,000 instead of the gamble on the risky policy. It may be appropriate to use this certainty equivalent in the summation of benefits and costs. But, the value of a certainty equivalent depends on society's degree of risk aversion, which is difficult to estimate.

The analyst may account for the degree of risk aversion by adjusting the discount rate in the discounting formula applied to the mathematically expected future values.^[12] For risky benefits in the future, the discount rate, r , should be increased, and, for risky costs in the future, the discount rate should be decreased. Increasing r makes the present value smaller to reflect the aversion to risk; the risky future benefit is not worth as much to us today as is a certain future benefit. The analyst should be clear about any risk adjustments to the discount rate. Sensitivity analysis should also be presented so the decision maker can evaluate the impact of adjusting for risk.

It is important to note that incorporating risk does not fully account for the problems of an uncertain future. Risk is a particular subset of uncertainty, where all possible outcomes are known and all of those potential outcomes have a known probability of occurring. However, for most public decisions, there are many outcomes that cannot possibly be known beforehand. Even if all possible outcomes are known, we may have to estimate the probability of each occurrence. Because of these unknown possibilities, benefit–cost analysis may recommend a project that, in hindsight, should not have been undertaken.

DISTRIBUTION CONSIDERATIONS

By using the dollar metric, benefit–cost analysis implicitly weights the estimation of benefits and costs among individuals, based on their wealth. An unadjusted benefit–cost analysis assumes that the distribution of wealth is optimal. If the distribution of wealth is not deemed to be optimal, then the benefits and costs of the policy can be reweighed to compensate for any wealth bias. Reweighing can be based on the overt statements of elected officials, or the new weights can

be estimated in an attempt to align “economic votes” with democratic votes, in which each individual counts the same. In the former case, politicians may clearly state that the preferences of the poor or disadvantaged minorities should be valued more than others. In the latter case, benefits and costs accruing to the wealthy are discounted. The final report should be clear about the distributional aspects of the policy. The analyst should conduct and report on the sensitivity of the reweighing procedure.

CONCLUSION

Benefit–cost analysis is not cheap, easy, or quick. If analysts try to track and quantify every possible consequence, they will never finish. Implicitly, every analyst must conduct a benefit–cost analysis of the benefit–cost analysis. Additional information may not be worth the price of obtaining it or of delaying the report. It is also important to recognize the possibility that benefit–cost analysis can be requested by policy makers to delay policy implementation rather than ascertain the policy's efficiency.

Benefit–cost analysis can successfully aid public decision makers when assumptions and sensitive methodological choices are clearly stated. As benefit–cost analysis gains popularity with policy makers, those affected, such as public administrators, public advocates, and concerned citizen groups, will increasingly need to understand the nuances of this and other quantitative decision-making aids.

Reciprocal Relations Among Peace, Prosperity, and Democracy

Stuart S. Nagel

Political Science Department, University of Illinois, Urbana, Illinois, U.S.A.

INTRODUCTION

The leading controversial policy issues in developing nations like those of South Asia tend to be economic, political, and military in nature. The economic issues relate to making domestic economies more prosperous and facilitating investments, exports, and imports. The political issues relate to promoting democratic institutions, human rights, and self-determination. The military issues relate to advocating non-proliferation of arms and reduction in regional conflicts.^[1]

The purpose of this article is to discuss some aspects of U.S. foreign policy as applied to these policy problems of developing regions and nations.^[2] The context is in terms of win-win thinking where all nations involved are better off as a result of the interaction.^[3] The context is also in terms of three tables, which give useful visual aids to clarify the mutually beneficial interaction.

TEN CAUSAL RELATIONS

The first six causal relations in [Table 1](#) can be interpreted as follows:

1. Reduction in military conflicts is conducive to prosperity and investment.
2. Prosperity is conducive to reduction in military conflicts, especially prosperity based on buying and selling across countries that might otherwise be in conflict.
3. Prosperity is conducive to democratic institutions, human rights, and tolerance of minority ethnic groups.
4. Democracy, human rights, and ethnic peace are conducive to prosperity.
5. Democratic political institutions are conducive to a reduction in military conflicts.
6. Reduction in military conflicts is conducive to democratic political institutions.

The last four causal relations can be interpreted as follows:

7. U.S. policy is concerned with encouraging prosperity, investment, exporting, and importing because doing so is mutually beneficial.

8. U.S. policy is concerned with reducing military conflicts partly because of the favorable effect on prosperity and the economic issues.
9. U.S. policy is concerned with promoting a democratic political environment partly because of the favorable effect on prosperity and the economic issues.
10. U.S. domestic economic policy emphasizes U.S. prosperity and gross national product (GNP) growth, which partly explains why U.S. international policy emphasizes mutually beneficial trade and investment opportunities.

Miscellaneous points include:

1. In the context of South Asia, Pakistan is especially concerned with military security, India is especially concerned with political issues, and Sri Lanka is especially concerned with international economics, but all three countries are concerned with all three sets of issues.
2. The concept of mutual benefit is promoted through regional organizations, such as the South Asia Association for Regional Cooperation, as well as through interregional interaction between South Asia and the United States.
3. Social issues such as poverty and ethnic groups are also important, although they are considered under economic and political issues, respectively. Technology issues are also quite important, but they are discussed in the context of military, economic, and political issues.
4. There are positive relations among all five variables shown in Table 1. Those relations are positive in the sense of upward causation and being desirable relations, especially regarding the promotion of peace, prosperity, and democracy.

HISTORICAL DEVELOPMENT

The past was characterized by colonialism and the Cold War. The present is being characterized by investment, importing, and exporting of funds and foods. The future may be characterized by transfer of technologies and skills from the United States, which

Table 1 Win-win U.S. foreign policy

NOTE: All relations are positive. Thus there is no need for a plus sign on each arrow. For example, Relation 2 says prosperity causes peace because in time of depression, political leaders sometimes look for external enemies to distract people from being unemployed.

results in mutually beneficial investment—returns, buying, and selling. Those basic ideas are summarized in Table 2.

The arrows from the *past* indicate:

- (1 and 2) Colonialism-involved low wages going to the developing nations, and valuable resources going to the United States or other industrialized nations.

- (3 and 4) The Cold War—involved arms and aid going to developing nations, and allegiance going to the United States or the Soviet Union.

The arrows from the *present* indicate:

- (5 and 6) Capital investment going to the developing nations with a reasonable return going back to the United States.

Table 2 U.S. foreign policy for 200 years

NOTE: Unlike Table 1, the arrows here are not causal arrows. The arrows on the left side show what the U.S. has generally received from its relations with developing nations in the past, present, and future. The arrows on the right side show what developing nations have received from the U.S.

- (7 and 8) Cash or credits going to developing nations in return for their products.
- (9 and 10) Products going to developing nations in return for their cash or credits.

The arrows from the *future* indicate:

- (11 and 12) Technologies and skill go to developing nations, thereby improving their ability to be good places for investment, buying, and selling.

In the past, there was often an imbalance, with disproportionate benefits to the industrial nations and disproportionate detriments to the developing nations. In the present, there is generally mutual benefits from investments, exporting, and importing. In the future, the transfer of technologies and skills may enable all participating countries to exceed their best initial expectations simultaneously.^[4]

ILLUSTRATIVE EXAMPLES

Tables 3–5 show how win–win analysis might be applied to three key issues in South Asia. The issues relate to trade vs. aid, secession, and nuclear arms.

Trade Vs. Aid (Prosperity)

The United States currently tends to favor trade over aid because trade is more mutually beneficial than aid, which tends to mainly benefit the recipient nation unless there is a Cold War return.

Developing nations tend to favor aid with no strings attached, at least in the past, because they are fearful that^[1] buying from the United States will disrupt local industries, and that^[2] they have little to sell to the United States.

Table 3 Trade vs. aid in South Asia

L	–	+
1. Retain rebellious provinces (pro-India)		
2. Release rebellious provinces (pro-Pakistan)		
N Partition	0	0
SOS or win–win	++	++
Autonomy like a U.S. state		

Skills and technology transfer greatly benefit the United States by virtue of improving places for 1) U.S. investment; 2) the buying of American products; and 3) the selling to the U.S. of products needed by the American people. Skills and technology transfer benefit developing nations by enabling them to upgrade their international competitiveness even more than offering them either trade or aid.

Seceding (Democracy)

The United States tends to favor self-determination out of a regard for democratic decision making, emphasizing the majority will within the rebellious provinces.

Developing nations tend to favor retaining their own rebellious provinces, emphasizing the majority will within the larger political entity.

Autonomy, like that of a U.S. state, refers to states having their own constitutions and governors that cannot be removed by Washington. States in India do not

Table 5 Nuclear arms in South Asia

2. Inspect		
SOS or win–win	++	++
Peaceful conversion		

have their own constitutions and their governors can be removed by New Delhi.

Nuclear Arms (Peace)

The United States tends to favor the removal of nuclear arms from South Asia for fear that their presence may lead to nuclear warfare, which might involve the United States directly or indirectly by way of international disruption.

Countries that have nuclear capability like India and Pakistan are reluctant to weaken their deterrent power against each other.

Peaceful conversion in this context means providing India and Pakistan with the skills and technologies for

converting their nuclear capability into peaceful and safe nuclear energy along with American investment funding.

Reduction in Force

Teva J. Scheer

University of Colorado at Denver, Highlands Ranch, Colorado, U.S.A.

INTRODUCTION

This article discusses the requirements and procedures that typically comprise reduction in force systems (RIFs) in government employment. It also briefly reviews the results of employee appeals resulting from RIFs, and closes with a few suggestions for administering an RIF action.

WHAT IS RIF?

An RIF is a systematic process that a government agency can use to reorganize or to reduce its staffing levels. The federal government, as well as many state and local agencies, have published rules and procedures that govern how they must conduct RIFs. These procedures are generally available for review by employees, unions, and even the public, thereby demystifying the process. There are four general reasons why an agency would choose, or be required, to conduct a RIF:

1. Lack of work for the existing work force.
2. Lack of funds to pay the existing work force. Short-term funding problems may be handled using furloughs or use of voluntary leave without pay, but longer furloughs (e.g., more than 30 days) often trigger the RIF mechanism.
3. A change in the number and type of positions needed as a result of reorganization. Reorganizations include Transfers of Function, in which a work unit or department is moved to a new geographical or organizational location.
4. The need to make room for an employee who has reemployment or restoration rights.

Even though most employees fear the negative impact of an RIF, it does provide an equitable mechanism for realigning an agency or reducing its workforce. It also allows an agency and its remaining employees to “move on,” i.e., return to normal recruitment and placement practices immediately. Many agencies decide to downsize or reorganize using attrition rather than RIF, but this strategy has at least two major and negative results:

1. Agencies may be required to suspend normal promotional opportunities during the period of attrition, thereby negatively affecting employee morale and career development.
2. Staff costs will be higher during the attrition period. The agency is likely supporting too many employees, and some of the employees will be in the wrong positions, wrong occupations, and wrong pay levels.

While the specific RIF procedures vary for each government system, typically the procedures require an agency to establish a “competitive area” in which employees will compete for positions. The competitive area may be described geographically, or organizationally, or both. Each competitive area is organized into “competitive levels,” which consist of all the positions within the competitive area that are sufficiently alike in qualification requirements, duties, responsibilities, pay schedules, and working conditions so that the agency may readily assign the incumbent of one position to any of the other positions without changing the terms of the employee’s appointment or unduly interrupting work. All the employees within a competitive level are placed in order on a “retention register.” Their order is determined by such factors as tenure, performance scores, and veteran status. If positions within a competitive level are abolished, the employees who are displaced are those with the lowest scores on the retention register. Employees who are thus displaced may have rights to “bump” an employee of lower retention standing in another competitive level.

RIF APPEALS AND CASE LAW

A review of RIF case decisions issued by federal courts, the Equal Employment Opportunity Commission, and the Merit Systems Protection Board showed that a substantial majority of RIF appeals are decided in favor of agencies.^[1] A notable exception was cases where the adjudicatory authority found that the agency had failed to follow its own guidelines or had committed a technical error in administering the RIF action. Agencies should also keep in mind that RIFs are subject to the requirements of the Uniform Guidelines on Employee Selection, so agencies should

exercise extra caution in following its procedures and in documenting all aspects of the RIF if it appears that the RIF will have adverse impact on members of a particular race, sex, or ethnic group. (See Uniform Guidelines on Employee Selection.)

Some of the RIF aspects that generally have been unsuccessfully challenged by affected employees include allegations that the agency

1. Had failed to prove RIF was based on one of the reasons outlined in the agency RIF procedures (e.g., lack of work, lack of funds).
2. Had established a competitive area that was improperly sized, or that the area's composition was inappropriate (e.g., it should have included additional positions).
3. Had improperly constructed its retention registers.
4. Had failed to satisfy the employees' assignment rights.
5. Had provided inadequate notice to employees as required in the RIF procedures.

MANAGING THE RIF PROCESS

The prospect of an impending RIF action has a chilling effect on employee morale and productivity. Often, management is reluctant to share information with employees in the early stages of RIF planning because the timing and impact are still so uncertain. Once rumors of an RIF begin to spread throughout the workforce, however, the best course of action is to share as much information as possible with employees and/or with the union that represents the employees. Most employees would rather be informed of details, even if they are subject to change, than to hear nothing from their managers.

Employees will naturally turn to their immediate managers for information. If the first-line managers have not been briefed by top management or by human resources, it will contribute to distrust and disaffection on the parts of employees and their managers. Therefore, the first-line managers need to receive briefings and the opportunities to get answers to the questions they will hear from their staff. Human

resources may wish to prepare a briefing document to guide first-line managers in conducting employee meetings. In addition, top management should take advantage of all communication vehicles on a regular basis: memoranda, e-mail, video systems, bulletin boards, employee websites.

If some employees will be separated as a result of the RIF, human resources should establish a counseling system to help them prepare for their lives after leaving the agency. Employees need to be given administrative time to prepare resumes. If possible, a private space should be set up outside the workplace where employees can meet with counselors, search for jobs, and prepare resumes. Employee sessions should be planned to share information about severance pay, health and life insurance benefit continuation, and any placement programs.

Employees who are separated or bumped to another position are subject to the stages of shock and mourning that were first identified by Elisabeth Kübler-Ross in 1969: shock, anger, depression, flight, and acceptance.^[2] Whether they are treated with compassion and respect may well have a substantial impact on the morale of those individuals who remain agency employees.

Regulatory Policy: Role and Importance

Scott R. Furlong

*Public and Environmental Affairs, University of Wisconsin-Green Bay,
Green Bay, Wisconsin, U.S.A.*

INTRODUCTION

Regulatory policy is dominant in the United States. Most of the policies that affect American's everyday lives are probably a direct result of regulations from agencies such as the Environmental Protection Agency (EPA), Food and Drug Administration, or the Occupational Safety and Health Administration. Yet, most people do not think much about this important area of public policy. In fact, until the 1980s and the Reagan administration, regulatory policy was rarely mentioned in discussions of government and politics. We still tend to focus on statutory laws without recognizing that the implementation of those laws is where the proverbial "rubber hits the road." The passage of the Occupational Safety and Health Act did not directly make the workplace safer, but regulations issued by OSHA did and continue to do so. This article examines the evolution and role of regulatory policy in the United States, as well as the obvious importance of this type of policy in our daily lives.

CONTROVERSIES AND DEFINITIONS OF REGULATION

We all have some intuitive sense about what the term regulation means. Often this sense is driven by our ideological beliefs about the role of government in our daily lives. Conservatives, and many Republicans, see regulation as government interference or intrusion upsetting the free market and imposing undue costs on business and society. For liberals, and many Democrats, regulation is seen as government authority to protect the general public from unfair and unsafe practices of corporate America. It is clear that both of these insights are tainted by one's philosophical beliefs.

Eisner et al. define regulation as "an array of public policies explicitly designed to govern economic activity and its consequences at the level of the industry, firm, or individual unit of activity."^[1] This definition obviously is more neutral and describes the actual activity occurring. It also raises a common way to examine types or varieties of regulatory policy. These characterizations of regulatory policy are often referred to as economic regulation and social regulation. Economic

regulation, the more traditional of the two, focuses on the role of a firm in a market. From the general public's perspective, economic regulation tries to protect consumers from the adverse effects of monopolistic practices that can have an adverse impact on consumers. Regulation in this area tends to focus on single industrial sectors, such as broadcasting, railroads, and the stock market. Although economic regulation might be considered the more traditional of the two types, most people when they consider regulatory policy, associate regulation with social regulatory policy. Social regulation tends to focus on the activities of industry in the production of its products. Many of the policies in this area focus on the negative externalities (spillovers) that result from production, such as workplace health and safety issues and environmental protection. In general, many of our social regulatory policies, unlike economic regulation, are broader in their application and do not focus on a single industry. As an example, workplace safety regulations can potentially affect every industry and firm that is trying to meet a particular regulatory criterion set by the agency.

Attacks against regulatory policy often focus on social regulatory policy. In many ways, the Reagan administration typified these attacks, claiming that excessive regulation in this form led to problems with the economy. Simplistically, because businesses needed to install protections of various sorts to comply with these regulations, they were increasing their cost of production and ultimately having a negative impact on the overall economy. Because many social regulatory policies are not industry specific, the impact of workplace safety and health regulations, for example, could be huge. Therefore, to improve the economy, many conservatives believed that there was a need to deregulate in the social regulatory policy area, much like it was done with some economic regulatory policy in the 1970s.

The 1970s did see a strong movement toward deregulation, but as stated, it focused on industry-level regulation. The prime example was the deregulation of the airline industry, around which an interesting coalition developed. Conservatives were supportive of deregulation and of allowing the market to work on its own on the basis of its merits. Liberals believed that deregulation would cause airline ticket prices to

decrease and allow air travel to become accessible to more people. The competition introduced as a result of deregulation (as well as other forces) led to the desired goal in the airline industry—more competition and prices that were likely lower than they would have been otherwise.

Increased competition, though, does not necessarily lead to the desired goals of social regulation. Many social regulatory policies deal with a market failure called a negative externality. A negative externality occurs when two parties interact in a market transaction, and when a third party is adversely affected by this transaction and not compensated for their loss. For example, producing electricity causes air emissions that may adversely affect the health of those downwind. Increasing competition, such as when the airline industry was deregulated, will lead producers to decrease prices to attract consumers. To do so, they will want to reduce their costs of production, which many times are the controls installed to protect society. For example, pollution control technology is installed to reduce pollutants from the processing stream, but this adds to the cost of doing business. Deregulating in this area could mean that businesses do not install these controls (to save money); therefore, pollution emissions are increased.

In general, it appears that the general public supports many of our social regulatory policies. Public opinion polls continually show strong support for environmental and consumer protection policies. There was a significant backlash against the Reagan administration after his attempts to lessen social regulatory policy, especially by the Democratic House of Representatives. A similar backlash occurred against the Republican Congress in 1995 when they attempted to reduce funding in these areas, particularly for environmental protection. Therefore, one can see significant conflict in this public policy arena. Increases and decreases in the extent of regulatory policy tend to generate much debate these days especially at the macropolicy level.

Another issue often raised in regard to economic regulatory policy specifically is the issue of agency capture. Numerous scholars began analyzing the role of regulatory agencies and their relationships with the businesses they were tasked by Congress to regulate. Bernstein's analysis discussed that at some point in an agency's "life cycle," it begins to be more concerned with the health of the industry than with the interests of the general public.^[2] Others also examined the potential issues associated with capture, and many believe that one of the arguments for deregulating the airlines was the concern about capture.^[3,4] Other scholars used the capture argument as evidence and reasons as why extensive delegation of regulatory power was problematic.^[5,6]

Regulatory policy is not without its issues. These issues range from the economic—how these types of

policies can affect economic growth in the United States and health of industries—to the democratic—whether so much power should be given to unelected agency officials primarily responsible for developing regulatory policy. These issues are not new and have been around for almost as long as the existence of regulatory policy (as we currently think of it) itself.

EVOLUTION AND STAGES OF REGULATORY POLICY

Scholars often examine the evolution of regulatory policy in the United States in four distinct stages. The first stage occurred in the late 19th/early 20th century, which saw the creation of the first independent regulatory commission, the Interstate Commerce Commission. Much of this early regulatory policy was strictly economic in scope in that it focused on the private activities of businesses and attempted to control potential monopolistic behavior. Other agencies such as the Federal Trade Commission followed, and again the focus was on the protection of the consumer from unfair labor practices. The second regulatory stage corresponds to the New Deal era. The New Deal era ushered in a much more extensive role for the federal government in our daily lives. This was exemplified by the increasing number of federal agencies, many of them regulatory in nature. Many of the regulatory policies during this time, not surprisingly, were geared toward economic recovery, and many of the policies continued to examine the role of competition in various industries.

The policies of the New Deal and how these policies were created laid the groundwork for the third stage of regulatory policy—the rise of social regulatory policy in the 1960s and 1970s. As mentioned earlier, social regulatory policy is quite a bit different than economic regulatory policy. The goals of social regulatory policy are much more expansive and typically far reaching, and tend to deal with issues of health, safety, or equal opportunity. Wilson classified many of these policies as those that have concentrated costs and diffused benefits.^[7] The costs of the policies are (typically) borne by a few businesses, but the benefits are provided to many. These regulatory policies continued the expansion of the federal role in the United States. Now the government was regulating the safety of consumer products, the workplace safety conditions, and quality of the water among many other areas, and it was not doing so as a way of promoting competition. Rather, the expressed purpose of these policies was the physical protection of the general public from products and industrial processes.

The fourth stage, which we may still be in, encompasses the era of deregulation (discussed earlier) and

various attempts of regulatory reform that followed. The deregulation of many of our industries also fueled similar ideas in the area of social regulation. Numerous regulatory reform efforts promoted and implemented by different administrations have had a profound impact on regulatory policy since the mid-1970s. Often, these reforms have been focused on the management of the rule-making processes used by agencies and the use of analyses to better inform regulatory decisions. President Reagan's Executive Order 12291 is the best example of both these efforts. This executive order initiated elaborate rule-making reviews by the Office of Management and Budget (OMB) and also required agencies to conduct benefit-cost analyses for major rules and take this information into consideration when making decisions. Similar analytical and managerial requirements would follow that affected not only the quantity of regulations issued by federal agencies, but also the nature of the debate within agencies.

The introduction of economic analyses in the development of regulations and the use of these analyses to help in decision making brought to the forefront the idea that regulatory policies may have a detrimental impact on the economy. Different administrations used these arguments in their attempts to decrease the amount of regulatory activity from the agencies. This was especially true during the Reagan administration, which showed major reductions in the number of rules coming out of federal agencies compared with the Carter administration. Managerial changes attempted to centralize the rule-making process, as well as to provide more oversight to the President and his staff, to ensure that agencies were following the administration's goals and agenda. The OMB was used as a clearinghouse for many regulations by reviewing them prior to an agency issuing the policies. The activities of the OMB, and later President George H. Bush's Council on Competitiveness, had the effect of requiring agencies to make changes to their regulations to follow the administration's ideals or having their policies delayed for extended periods of time. Agency behavior changed so that they would give more careful consideration to the development of agency regulations to ensure that they would pass the new administrative hurdles placed in front of them. Economic shops within agencies were expanded and given additional authority to develop and review regulations internally. Now that past presidents have created and used the OMB as a way of monitoring agency rule making, any future president would be crazy to abolish such functions. They may redefine their role or the types of regulations being reviewed, but all would want to keep these mechanisms in place to take advantage of the possibility to influence policy at this level. In addition, presidents also have the ability to change policies dramatically without going through the process of

getting new laws passed by using changes in regulations to pursue their agendas.^[8]

REGULATORY POLICY NOW AND IN THE FUTURE

This article began by stating that regulatory policy is dominant in our daily lives. If you do not believe this, try thinking about your day-to-day activities and how the most mundane activities are likely affected by policies developed by regulatory agencies. The car you are driving must meet certain safety standards imposed by the Department of Transportation. The labels on your groceries are a result of work by the Food and Drug Administration. OSHA governs your workplace in terms of safety and health issues. It is clear that regulatory policy is here to stay, but will we see some changes?

One area where we may continue to see movement in regulatory policy relates to the issue of private or self-regulation. This term has a number of meanings, but one can think of this as a continuum of the amount of control entities have in regulating themselves or ensuring the implementation of regulations placed upon them. This is not a new idea; in fact, there have been some implicit and explicit federal policies to encourage this form of regulation. One example of private regulation is the movie industry's rating system for content. This is an area where the government has allowed the industry and its professional organization to regulate itself. Some agencies have attempted to move in the direction of acting as a consultant for the areas in which they regulate in order to facilitate achieving the desired results. Under President Clinton's National Performance Review, for example, OSHA provided businesses with the option of forming a partnership with the agency; through this partnership, businesses "would receive technical assistance and consultation" from OSHA.^[1] Might we see more of these types of activities and relationships between government and business? This type of relationship suggests the government as a facilitator and a resource to help businesses reach regulatory goals, rather than an adversarial relationship.

A related change that is likely to continue into the future is an increase in public participation methods and the use of alternative dispute resolution programs. Again, these are not new programs. For years, agencies have explored different ways to increase participation in the development of their regulations and policies. One of the primary components of the Administrative Procedure Act are requirements for this participation. Agencies have also explored alternative means to reach consensus or decisions in regard to their policies. Many have lauded the potential of processes such

as regulatory negotiation for a number of years.^[9,10] Agencies have continued to build upon these alternative methods of gathering input and data on their policies. They have also been used to work with the regulated community to attempt to reach mutual decisions. The EPA is one agency that has attempted a number of these process reforms to improve its policies and relationships. The EPA has been one of the leaders in the use of regulatory negotiation processes in their rule development. In addition, it has used numerous alternative dispute resolution processes with varying levels of success.^[11] Its Project XL is another example of a program designed to encourage increased and early participation. Under this program, the EPA works with the major stakeholders in a particular area to develop more cost-effective ways of achieving environmental protection. Recently, the EPA has also experimented with the use of online democracy by using the Internet as a way of increasing the amount of participants dialoging on a specific policy.^[12] One can expect that programs that encourage greater participation and focus on more conciliatory relationships will continue throughout regulatory agencies. They may not always be successful or even engender good will between business and government, but they are potential steps in the right direction. Critics may argue that these types of relationships raise the possibility of a type of capture that needs to be avoided to protect the general public.

Related to these efforts by the EPA are increased efforts by a number of agencies to use the Internet as a way to increase participation through the traditional notice-and-comment rule-making process. These efforts have made it easier for organizations and individuals to learn about potential rule-making efforts through websites such as Regulation.gov, which also provides a simple format in which to send comments to agencies. In addition, a number of agencies such as the Department of Transportation and the EPA are making their rule-making dockets available online and hence providing better access to information and other comments to those interested in participating.

CONCLUSION

This article has discussed numerous issues regarding regulatory policy. It is clear that regulatory policy is

pervasive in our daily lives and will continue to be so in the future. It is also clear that there are different forms of regulatory policy. There is a vast difference between economic regulatory policy, which started the regulatory era, and social regulatory policy, which is now much more common. In addition, people have different beliefs and concerns about the role of this policy. The debate will continue about the impact of regulatory policy, and we can expect numerous reforms to also continue to enter into the debate. The political, economic, and ethical concerns of this important area of public policy will continue to challenge scholars as long as the public continues to demand services and policies from government.

Representative Bureaucracy

Katherine C. Naff

*Public Administration Program, San Francisco State University,
San Francisco, California, U.S.A.*

INTRODUCTION

The term representative bureaucracy refers to the notion that government agencies should mirror the composition of the population they serve. Former President Clinton summarized the concept when he promised a government that would “look like America.” In saying that, he was referring specifically to the idea that his appointed officials would reflect the gender and racial diversity of the American population. That the federal civil service should also reflect this diversity has been the policy of the U.S. Government for nearly three decades.

This entry discusses the origin and development of the concept and the reasons that have been proffered for the need to ensure a bureaucracy that is representative. It further discusses controversies over how such representation should be defined and measured as well as empirical research that has substantiated the notion that representation can make a difference. It concludes with some thoughts about directions for future research.

THE BIRTH OF A THEORY

Original notions of bureaucracies, as developed by Max Weber in his essays, saw them as ideal organizational structures in a democratic environment because they are objective and business is carried out according to rules, in a “dehumanized” way. Thus, all citizens are treated equally. And yet at the same time there is an inherent contradiction between bureaucracies and democracy. They are staffed by civil servants who are responsible for developing and enacting policies within the broad parameters of laws passed by Congress, but these civil servants are unelected and not directly accountable to citizens.

With that concern as a backdrop, scholars came up with various prescriptions as to how to make bureaucrats more accountable, including strengthening executive and/or legislative control. But Kingsley, who coined the term “representative bureaucracy,” was not convinced this was feasible. Writing about the British government during the second World War, he noted that it was the middle class origins of the

civil servants that rendered them able to carry out the government’s policies because the political party holding office shared their social origins. But when the working class Labour Party assumed power, their policies would not be carried out successfully by the middle class civil servants. In his 1944 book he wrote:

[T]he essence of responsibility is psychological rather than mechanical. It is sought in an identity of aim and point of view, in a common background of social prejudice, which leads the agent to act as though he were the principal. . . . No group can safely be entrusted with power that do not themselves mirror the dominant forces in society.^[1]

Kingsley did not apply his concept to American politics, nor did he articulate very well the benefits of a representative bureaucracy.^[2] Other scholars, however, stepped into this breach and further clarified and strengthened his focus on the men and women who comprise the civil service.

THE AMERICAN SCENE

Levitan was the first scholar to take hold of Kingsley’s notion and apply it to the American landscape.^[3] He agreed with Kingsley that external controls were too inflexible to be relied on to control the modern bureaucracy. Other adherents to the theory included Long who suggested that “the rich diversity that makes up the United States is better represented in its civil service than anywhere else,” including Congress.^[4] Others were less enthusiastic about the notion, arguing that it is not necessarily the case that bureaucrats retain the values of their social origins, nor that a representative bureaucracy guarantees that all of society’s interests are taken into account.^[5–7]

Krislov stepped into the debate and suggested that a representative bureaucracy serves other laudable purposes besides serving as a restraint on bureaucratic power.^[8] It:

- Includes a broader array of skills that can augment its ability to address a broader range of social problems;
- Acts as a funnel for very different viewpoints;

- Shares social responsibility, resulting in a broader approval of governmental policies;
- Demonstrates that all have access to government positions; and
- Ensures that even members of disadvantaged groups will be encouraged to gain the education and other qualifications necessary to serve in public office.

“Bureaucracies, by their very structure,” Krislov wrote, “represent truths about the nature of the societies and the values that dominate them” (p. 64).

If a representative bureaucracy provides these other benefits, then, the debate as to whether bureaucrats indeed preserve the values associated with their social origins is less important since a diverse civil service also serves an important symbolic role.

But what characteristics should a bureaucracy display if it is to be considered representative? Most of these early scholars, including J. Donald Kingsley, saw a representative bureaucracy as one that shared the social class origins of the citizenry, and concluded that the federal civil service was indeed representative.^[4,5,9] However, in the United States, with the vocal women’s rights and civil rights movements of the 1960s, that orientation gradually shifted from social class to one where the concern was for sufficient women and minorities to be represented in the bureaucracy. There were a number of reasons for this, including a history of discrimination against these groups in the government (as well as society in general.) Moreover, as government had responsibility for enforcing equal employment opportunity legislation passed by Congress, it had to ensure its own house was in order in this respect. With the passage of the Civil Service Reform Act of 1978, it became the official policy of the U.S. Government to provide a “federal workforce reflective of the nation’s diversity.” The Act further directed agencies to make efforts to eliminate the underrepresentation of people of color and women in all occupations and at all grade levels (5 U.S.C. § 7201).

The federal government has had considerable success in recruiting women and people of color. By the end of fiscal year 2004, women held 43%, and people of color held 33% of permanent federal government jobs.^[10] Whether these percentages mean that the government is indeed representative, however, is not a simple question to answer.

ASSESSING THE QUANTITY AND QUALITY OF REPRESENTATION

Counting the Numbers

The percentages cited above denote what has been called “passive” representation.^[11] Some scholars have

argued that these numbers signifying the overall representation of people of color and women are not good enough. If these groups are to have a real voice in policy making, they must be well represented in senior level jobs. As a result, scholars as well as federal agencies assigned to the task [e.g., the U.S. Office of Personnel Management (OPM) and the Equal Employment Opportunity Commission (EEOC)] also track the proportion of women and people of color in higher level jobs. It turns out that in these jobs, these groups are not as well represented (see Fig. 1). At the end of fiscal year 2004, men held 74%, and whites held 86% of senior pay positions in the federal government.

However, another problem in defining the extent of representation is that there has never been a fully agreed upon way to measure representation. While some early scholars believed the percentage of women and people of color in the bureaucracy should be equal to their representation in the population, the EEOC and OPM employ a more limited benchmark.^[10,13] For these agencies the point of comparison is the civilian labor force (CLF), which includes all people in the United States who are at least 16 years old and not employed by the military. As shown in Table 1, by this measure Hispanic men and women and White women are underrepresented in government. All other groups are fully represented.

However, even these two agencies use different numbers to compute representation. The EEOC includes federal agencies that are not included in OPM’s calculation of government representation, and while OPM includes Puerto Rico in its estimation, the EEOC does not. So, while the EEOC reported that Hispanics represented 7.46% of the

Fig. 1 Representation of men, women, and minorities in senior pay level positions in the Federal Government (FY 2004). (From Ref.^[10]).

Table 1 Representation of racial and ethnic groups in the federal workforce and CLF (%)

	Representation in federal workforce (2004)	Representation in CLF (2000)
Hispanic males	4.48	6.20
Hispanic females	2.98	4.50
White males	40.71	39.00
White females	26.19	33.70
Black males	7.81	4.80
Black females	10.37	5.80
Asian American/Pacific Islander males	3.32	2.10
Asian American/Pacific Islander females	2.46	1.90
American Indian/Alaskan Native males	0.77	0.50
American Indian/Alaskan Native females	0.90	0.50

(From Ref.^[10].)

federal workforce and 10.7% of the CLF in 2004, OPM reported that Hispanics held 7.3% of federal jobs and 12.6% of the CLF in the same year.^[10,13]

Some scholars are even critical of these measures and have proposed others. In a 1973 publication, Nachmias and Rosenbloom suggested a Measure of Variation that compares the total number of differences within a group to the total number of potential differences.^[14] The U.S. General Accounting Office has advocated the use of a “ratio-based approach” that compares the numbers of women and each ethnic group to a benchmark group such as white men.^[15] Even counting the numbers, then, is not a simple matter.

Looking for Action

These measures of passive representation have been criticized for another reason. There are those who argue that passive representation is pointless unless it results in “active” representation.^[11] That is, there must be evidence that these so-called representatives are actually acting in the interests of the groups they are presumed to represent. Some research has indeed found bureaucrats playing such a role, although some has not. For example, Hinderer and colleagues have found that the greater the number of African American and Hispanic field investigators in EEOC offices, the greater the likelihood that complaints brought by African Americans and Latinos, respectively, will be pursued.^[16,17] Selden found a similar positive correlation between the representation of Hispanic, African American, and Asian American county supervisors in Farmers Home Administration Offices and the number of favorable eligibility decisions for loan applications filed by members of these groups.^[18,19] Meier and colleagues have identified an inverse relationship between the proportion of African American and Hispanic school teachers and school board

members and the incidents of disciplinary actions taken against students in these groups.^[20–22] It should be noted, however, that such relationships have not always appeared as expected. For example, Hinderer found a negative relationship between the number of white women investigators with the EEOC and the number of complaints filed on behalf of women.^[23] Selden found neither the representation of women nor Native Americans were related to loan eligibility determinations for members of these groups.^[19]

Clearly it would be beneficial to continue to add agencies to this investigation of the relationship between passive and active representation. But while this research is promising, it is also limited in that it only looks at the subset of government employees who work directly with citizens. Yet there are hundreds of thousands of bureaucrats who hold other significant policy making and implementation roles. Research in a range of fields, including psychology, sociology, and public administration, has revealed subtle ways in which the authority and influence of people in such positions can be limited.^[24] More research is required to ferret out the nature of such constraints and to hopefully identify the means for eliminating them.

CONCLUSION

The exceptions notwithstanding, scholars have found considerable evidence, at least among bureaucrats who are involved in direct client service, that passive representation does provide benefits in the form of additional assistance to those being represented. In addition, as Samuel Krislov has suggested, there are additional benefits served by a representative bureaucracy. These include improved policy formulation because of the diversity of viewpoints and experiences brought to bear and the increased legitimacy of the government as the nation’s largest employer and

enforcer of its equal opportunity laws. Once only a theory advocated by scholars, a federal statute now calls for a civil service “reflective of the nation’s diversity” and agencies such as the EEOC and OPM are charged with monitoring the extent to which this objective is achieved at all grade levels. Future research should continue to examine the ramifications and value of a representative bureaucracy, while also assessing the extent to which those benefits are being limited by barriers to the full authority and influence of women and people of color.

Restorative Justice

Michelle Maiese

University of Colorado at Boulder, Boulder, Colorado, U.S.A.

INTRODUCTION

The dominant understanding of crime and justice in the United States is shaped by a retributive framework. This framework focuses on the establishment of guilt and understands crime as a matter of lawbreaking and an offense against the state. When a law is broken, this creates a debt that must be repaid to society. Offenders must receive their “just desserts” and endure their punishment. The United States has established elaborate legal mechanisms to administer “just” doses of pain to those who have willfully broken the law.

Restorative justice, on the other hand, understands crime as an offense against real people and relationships rather than the state. Making things right requires healing victims’ wounds, restoring offenders to law-abiding lives, and repairing the harm done to interpersonal relationship and the community. Moreover, restorative justice recognizes that victims, offenders, family members, and affected communities are all key stakeholders in the restorative process and should play an active role in deciding how to repair the damage caused by the offense. Restorative justice thus represents a progressive way of thinking about crime and justice. The alternatives to punishment that it suggests can help to empower and heal victims, offenders, and communities (Table 1).

NEEDS OF VICTIMS, OFFENDERS, AND COMMUNITIES

The safety, support, and healing of crime victims are the starting points for any restorative justice process. A primary objective is to attend to victims’ needs: material, financial, emotional, and social.^[1] Victims need to receive compensation for any property they have lost and any physical injuries they have suffered. Other central victims’ needs include security, dignity, social support, and the sense that justice has been done.^[2] They must have the opportunity to tell their story and express their feelings about what has happened. They also need to feel vindicated and to know that others recognize what happened to them was wrong.

Restitution often plays a central role not only in restoring material losses, but also in acknowledging wrongdoing. Restitution agreements symbolize the fact

that offenders accept responsibility for the harm they have caused and wish to make amends. However, rather than focusing on punishing or defeating the wrongdoer, restitution aims to elevate the victim.^[3] Restorative justice therefore advocates restitution to the victim by the offender rather than retribution by the state against the offender. Instead of causing further harm, it tries to restore relationships and stop the cycle of violence.^[4]

Restorative justice also requires that victims be empowered. Because our current system defines the state as victim, this typically means that actual victims “are mere footnotes to the criminal justice process” and do not play an active role in their own cases.^[3] Restorative justice, on the other hand, acknowledges that because part of the harm victims have suffered is loss of power, one dimension of justice is ensuring that this power is returned to them. Victims must have access to information about who the offender is, why they were targeted as victims, and what is being done about the crime. They must also have the opportunity to engage in dialogue with offenders. Victims should play an active role in directing the exchange that takes place and defining the responsibilities and obligations of offenders.

Offenders are likewise encouraged to participate in this exchange, to understand the harm they have caused to victims, and to take active responsibility for it. Both the rehabilitation of offenders and their reintegration into the community are vital aspects of restorative justice. Restorative processes encourage offenders to understand and acknowledge the harm they have caused and assume responsibility for making things right. This means making an effort to make amends for their violations by committing to certain obligations: reparations, restitution, or community work. In addition, offenders should share in the responsibility for deciding what needs to be done to repair the harm they have caused. This may increase their sense of accountability.

While fulfilling these obligations may be experienced as painful, the goal is not revenge, but rather the restoration of healthy relationships between victims, offenders, and communities. Moreover, if offenders can play an active role in the justice process and take responsibility for what they have done, this can contribute to their rehabilitation. Removing offenders

Table 1 Comparison of retributive and restorative justice models

Retributive justice	Restorative justice
Crime is a matter of lawbreaking and an offense against the state.	Crime is an offense against individuals, relationships, and communities.
Those who commit crimes freely and willfully break the law.	Those who commit crimes act within a specific context. In many cases offenders themselves have suffered harm.
The process focuses on the establishment of guilt and is oriented toward the past.	The process focuses on offenders taking responsibility and is oriented toward the future.
To make things right, offenders must receive their “just desserts” and undergo pain.	To make things right, the harm caused to individuals and communities must be repaired.
Responding to crime centers on punishment.	Responding to crime centers on healing.
Victims’ needs are peripheral.	Victims’ needs are central.
Legal personnel process cases. Victims and offenders do not play an active role in the justice process.	Victims and offenders play an active role in determining outcomes.

from the community, or imposing any other severe restrictions, should be viewed as a last resort. The best way to prevent reoffending is reintegration.

Restorative justice is a forward-looking, preventive response that strives to understand crime in its social context. Although offenders are responsible for the harm they have caused, their behavior arises out of a social, economic, and psychological context. Moreover, crime often grows out of harm that the offender himself/herself has suffered. Restorative justice challenges us to examine the root causes of violence and the social conditions that give rise to crime.^[4] It suggests that communities must take some responsibility for remedying those conditions that contribute to crime and work to promote healing. This means transforming relationships and communities so that crime does not recur.

Restorative justice processes thus aim to strengthen the community and promote changes that will prevent similar harms from happening in the future. Many believe that the implementation of restorative justice processes can improve the quality, effectiveness, and efficiency of justice as a whole.^[3] A growing number of state and county justice systems in the United States have begun to incorporate “restorative” policies and programs (Table 1).

RESTORATIVE JUSTICE INITIATIVES

Restorative justice initiatives provide opportunities for dialogue and problem solving to interested crime victims and offenders so that they can more fully understand the events that have taken place. In short, the initiatives aim to put power and responsibility in the hands of those directly involved in the crime.

Such programs take on various forms. Victim–offender mediation is perhaps the most common and

involves face-to-face dialogues between victims and offenders. Group conferencing is an extension of victim–offender mediation and involves more participants, including family members of the victim or offender, community contacts, teachers, neighbors, or counselors. In addition, community victim-support organizations work to provide victims with material, psychological, and social support to aid in the healing process. Other organizations assist in reintegration for offenders and provide literacy education, employment services, counseling, and housing accommodation.

Research has shown that these restorative justice programs provide higher levels of victim and offender satisfaction than do traditional criminal justice programs.^[5] They are significantly more likely to result in victims’ perceptions that their cases were handled fairly and help to humanize the criminal justice experience.^[2] Below are more detailed descriptions of four restorative practices commonly used in North America and Europe: victim–offender mediation, group conferencing, community boards, and circle sentencing. These processes are non-adversarial, less formal than current criminal justice proceedings, and typically involve community members in planning and implementation.^[6] The continued development of such initiatives indicates that the range of services available for crime victims is expanding (Table 2).

Victim–Offender Mediation

Victim–offender mediation (VOM) provides interested victims the opportunity to meet with their offenders in the presence of trained volunteers who act as mediators. A central goal of VOM is to actively involve both victims and offenders in addressing the emotional and material harm that has been done. Through a face-to-face meeting, victims and offenders can develop

Q-Sexual

Table 2 Comparison of four restorative justice processes

	Victim–offender mediation	Family group conferencing	Community reparative boards	Circle sentencing
Key participants	Mediator, victim, and offender.	Victim, offender, their close family members and friends, police, and social service persons.	Reparative coordinator, community board participants, and offender.	Victim, offender, support persons, and relevant community members.
Prior to meetings	Mediators have face-to-face meetings with victims and offenders to explain the process.	Coordinators contact the offender, the offender's family, and the victim (either by phone or in person).	There is no preparation for individual hearings. Board members receive general preservice training.	Community justice committees work extensively with offenders and victims to prepare them for the process.
Role of facilitator	Mediator manages dialogue and keeps conversation flowing. Victim and offender do most of the talking.	The coordinator calls on each participant to describe the impact the crime has had on his or her life and ensures that all participants have a chance to speak.	Board chairperson dictates the course the meeting takes and calls on participants to speak.	“Keeper” simply initiates the conversation. Dialogue proceeds by passing the talking piece.
Decision of outcome	The victim plays a central role in shaping the restitution agreement. Both victim and offender must consent.	All participants, including offender, work together to determine how the offender can best repair the harm caused. Participants typically sign an agreement.	Board members develop a list of proposed sanctions. The offender agrees to fulfill obligations within a certain time frame.	Participants gather in a sentencing circle to develop a sentencing plan and identify the obligations the offender must fulfill.

Source: From Ref.^[6].

a better understanding of what has happened and work to develop mutually acceptable restitution plans.

This dialogue-driven form of “mediation” differs from traditional mediation insofar as the parties involved are not disputants and do not discuss the subject of guilt. Because the process is not focused on settlement, victims are not expected to compromise with respect to having their needs met and losses restored. Rather than passively taking their punishment, offenders take an active role in figuring out how to restore losses. Together, victim and offender determine the best way to repair the harms suffered.

Victim–offender mediation stresses the importance of extensive preparation for both victim and offender prior to the session. Before a dialogue takes place, the mediator meets with both offenders and victims to inform them about the process and invite them to participate. Preliminary meetings give the mediator a chance to establish credibility and rapport with the victim, provide information about the mediation program, describe the mediation process and its goals, and explain the possible benefits and risks of participation. Should the victim make an informed decision to participate, mediators also help to brainstorm about how losses and needs might be addressed. A dialogue with the offender should not be scheduled until the victim is ready and has realistic expectations about the process.^[7]

Meetings should occur in a structured setting in a location that victims consider safe. The dialogue itself should be structured so as to neutralize differences in status and power and ensure that both parties’ complete stories are heard. Parties are typically seated across from each other at a table, allowing them to have direct eye contact during the session. Support persons often accompany victims to the session to increase their sense of security and comfort. The mediator encourages participants to express their feelings and tries to facilitate an open dialogue in which victims and offenders do most of the talking. Although mediators must be careful not to intervene too frequently, they must also be prepared to step in immediately if a victim feels unsafe.^[7]

In addition to the option to terminate the meeting at any time, victims have many choices throughout VOM. They decide when and where to meet, who should attend, and what restitution plan best meets their needs. In addition to reimbursement of monetary expenses, the victim may request that the offender do community service, perform a personal service, write a letter of apology, participate in treatment or rehabilitation programs, or complete some creative assignment. While the final restitution plan must be negotiated with the offender, the process puts much decision-making power in the hands of the victim.

While VOM sessions typically result in signed restitution agreements, the dialogue itself is the most

important part. Victims have an opportunity to express their feelings, speak about the impact that the crime has had upon their lives, and receive answers to important questions about what occurred. The opportunity to come face-to-face with their offender increases the likelihood that victims will receive an apology and gain emotional closure.^[2] Offenders, on the other hand, come to understand the real human impact of their behavior and develop empathy for victims, which can help to prevent future criminal behavior. Thus mediated dialogue can satisfy the needs of the parties and aid in the healing process without resulting in a written restitution agreement.

At one time, people questioned whether victims would really want to meet with their offenders face-to-face. However, studies show that the majority of victims who are given the opportunity to engage their offenders in dialogue choose to participate.^[7] Victims who meet with their offenders are also significantly less fearful of being revictimized and report that the opportunity to be actively involved in the justice process results in a heightened sense of emotional closure.^[2] Research also indicates that offenders who meet with victims are more likely to fulfill their restitution obligations and less likely to commit future crimes.^[6]

As a result, the American Bar Association has endorsed the use of VOM and dialogue in courts throughout the United States. In 2001, there were approximately 320 victim–offender mediation programs in the United States and more than 700 in Europe.^[6] Many of the programs work only with juvenile offenders and handle mostly cases involving property offenses and minor assaults. However, advocates have begun to challenge the assumption that VOM is not suitable for violent or sexual crimes. Its use in these more serious cases is becoming more widespread.

Family Group Conferencing

Family group conferencing (FGC) involves all the people most affected by the crime: victim, offender, and the family and friends of both. The practice originated in New Zealand and emphasizes the role of family and community in addressing wrongdoing, reintegrating offenders, and holding them accountable. The process encourages the offender’s support system to take collective responsibility for making amends and shaping the offender’s future behavior. In addition to family members, conferences typically involve teachers, peers, and community resource people. Because conferencing involves more community members than VOM, some believe that it can contribute more to the empowerment and healing of the community as a whole.^[5]

Prior to the conference, the facilitator contacts both victim and offender to explain the process and

invite them to a conference. This in-person meeting provides an opportunity for coordinators to build trust, provide information, and prepare parties for the conference should they choose to participate. If victims and offenders are not prepared, they may not feel safe nor be able to participate freely in a genuine dialogue.

Once both parties have agreed to participate, they identify key members of their support systems to accompany them. With the help of the trained facilitator, the parties discuss how they have been harmed by the offense and how this might be addressed. After the offender has described why the crime occurred, each participant speaks about the impact the offense has had on his or her life. The offender is thereby faced with the real human impact of his/her behavior on the victim, those close to the victim, and his/her own family and friends. After this discussion, the victim helps to decide the obligations that the offender must carry out. All participants play a role in determining how the offender might fulfill these obligations and repair the harm he/she has caused. The session typically ends with participants signing a restitution agreement.

Family group conferencing is now being used in many states in the United States, including Minnesota, Montana, Pennsylvania, and Vermont.^[6] It is used primarily with juvenile offenders and in cases of theft, arson, minor assaults, and vandalism. Police people, probation officers, or school officials often act as facilitators. The process is most often used as a diversion from the court process and can often provide a much quicker and more satisfying resolution than traditional criminal justice practices.

Community Reparative Boards

Community reparative boards are primarily used with adult offenders convicted of non-violent and minor offenses. A small group of citizens who have received intensive training meet face-to-face with offenders (and sometimes victims) to discuss what has happened. During meetings, board members constructively discuss the nature of the offense with the offender and point out its negative consequences. A chairperson guides members through their questioning of the offender and their discussions with the other participants. The board members then propose and discuss a list of proposed sanctions. The offender agrees to take specific action within a given time period to repair the harm he or she has caused. A reparative coordinator, usually a State corrections employee, is responsible for monitoring the offender's compliance. This process enables offenders to take personal responsibility for what has happened and actually give something back to the community. It also reduces costly

reliance on formal justice system processes. However, some criticize reparative boards for their minimal involvement of victims.^[6]

Circle Sentencing

The practice of circle sentencing grew out of traditional sanctioning practices of aboriginal peoples in Canada and Native Americans in the United States. The first modern program was implemented in Canada and its use spread to the United States in 1996, when a pilot project was initiated in Minnesota.^[6] It is a holistic integrative strategy that aims both to address the delinquent behavior of offenders as well as to consider the needs of victims and communities. Crime victims, offenders, family, friends, interested community residents, and justice and social service personnel all gather together to develop a better understanding of the event. The process tends to enhance respect and understanding among all involved and often produces innovative solutions.

Circle sentencing demands extensive pre-session preparation. To be admitted to a circle, offenders must petition the community justice committee, visit a respected community member for a conference, and begin work on a reparative plan. This plan typically involves some restitution to the victim and community service. The pre-session procedures act as a screening mechanism to ensure that offenders take the process seriously.

Circle sentencing typically involves a multistep process. First, there are separate healing circles for the victim and the offender. Next, there is a sentencing circle to develop a sentencing plan. After that, there are follow-up circles to monitor the progress the offender has made. Participants are expected to take responsibility for monitoring the offender's compliance with the sentence. Throughout the process, community support groups work to fulfill the needs of victim, offender, and community. A central function of these support groups is to protect victims, provide them a sense of security, and hear their stories.

A trained community member called a "keeper" initiates the dialogue and ensures the process is followed. Participants sit in a circle and pass around a "talking piece." When it is their turn to talk, they explain their feelings about the crime and express support for the victim and offender. Central goals of the process include promoting healing of all affected parties, empowering victims and community members by giving them a voice in the process, and providing an opportunity for the offender to make amends.^[6] Circles also help to build a sense of community and address the underlying causes of criminal behavior.

CONCERNS ABOUT IMPLEMENTATION

Restorative justice is not yet a complete model. It is not entirely clear how it can address certain difficult issues, such as disputes over culpability, consequences of failure to reach an agreement, equity and proportionality in outcomes, or failure of the offender to comply with outcomes reached.^[2] Also, it seems the notion of restorative justice has been developed largely within a white, male, North American perspective and has yet to be tested in diverse cultures and traditions.^[3] Finally, it is unclear how restorative justice meshes with larger questions of social, economic, and political justice.

To prove successful, restorative processes must be highly sensitive to victims' needs. Programs that are overly offender-focused may treat victims simply as tools for rehabilitating offenders. In addition, restorative processes can perpetuate power imbalances already existing between victim and offender. Especially in cases where victim and offender have a prior relationship, power and coercion may operate in these informal structures to revictimize the victim. Facilitators must be careful not to exhibit bias toward the offender and to take the harms that victims have experienced sufficiently seriously. They must also be prepared to intervene should the victim feel threatened or uncomfortable. Processes that fail to adequately address victims' needs may have damaging effects.

Perhaps the most common argument against restorative justice practices is that the process and outcomes vary across programs, so that comparable crimes are not "punished" equally. Instead, restorative justice approaches yield individualized responses to crimes. This lack of uniformity contradicts some of our basic ideas about fairness. However, some suggest that issues of "fairness" could be mitigated if restorative justice initiatives were implemented system-wide. Furthermore, it seems that any worries that restorative processes might lead to random, inequitable, and overly severe sanctions are misguided.^[8] In fact, the emphasis of restorative justice on healing and constructive goals suggests that such initiatives would actually have the opposite effect.

There is some debate about whether restorative justice should remain an unofficial alternative to the criminal justice system or whether such practices should be implemented system-wide. Some maintain that restorative justice is not likely to have lasting, significant effects if it continues to operate primarily at the grassroots level. However, others suggest that even if restorative justice principles cannot transform the justice system, they may improve current criminal justice policies. Still others worry that government agencies will bureaucratize such initiatives and strip them of creativity. Spontaneity and grassroots ties are often what make these initiatives so successful.

Some advocate a double system of punishment, in which offenders are first processed through the traditional system and then move on to informal restorative justice programs to agree to a reparative contract. However, this may mean that they end up being subject to more sanctions. In addition, few resources will be saved if restorative initiatives are only a supplement to traditional punishment or are used only for minor crimes. It seems that for restorative justice initiatives to have a forceful impact, they must be implemented system-wide.^[8]

Without official encouragement and support, restorative justice programs are likely to be concentrated in neighborhoods with relatively minor crime problems and to be used only with fairly minor offenses. However, the empirical data suggest that programs increasingly handle cases involving adult offenders, more serious crime, and disadvantaged urban communities.^[8] Many believe that these experiments in applying restorative processes should continue. This will help to determine whether restorative justice is applicable in cases involving spouse and child abuse, rape, and murder, and what sorts of safeguards are needed. Testing of new programs will require creativity, risk-taking, and hard work.

CONCLUSION

To be sure, a restorative justice approach is not a realistic response in all situations. In cases where offenders are dangerous, it may be necessary to incarcerate and forego restorative tactics. There are also cases in which victims may experience meeting their offenders as threatening. In cases of emotional vulnerability, for example when victim and offender are well known to each other, a court process with its formality and impersonal procedures may be preferable.

However, the restorative justice paradigm shows promise of offering crime victims more justice than they currently receive in the dominant criminal justice paradigm. Such initiatives provide "alternatives to punishment which offer possibilities for accountability, repair, and empowerment."^[3] While traditional justice practices tend to ignore victims' needs and treat crime as an offense against the state, restorative justice recognizes that crime involves real-life individuals. Rather than simply inflicting more harm via punishment, it seeks to heal individuals and repair communities.

INTRODUCTION

Revenue prediction is a critical component of the budget-making process. Decision makers must know how much tax revenue they can anticipate in the upcoming budget period under existing tax laws, and how much revenue they can anticipate if there are tax law changes. This knowledge is especially critical for governments that are operating under balanced budget laws requiring equivalence between expenditures and revenues. Two types of revenue prediction are revenue forecasting and revenue estimation. Predicting baseline revenue collections under existing laws is known as “revenue forecasting.” Predicting the impact of specific tax law changes is known as “revenue estimation.” Revenue estimates are generally reported in “fiscal notes” accompanying specific proposed tax law changes.

RESPONSIBILITIES FOR REVENUE FORECASTING AND REVENUE ESTIMATION

Federal Government

In the federal government, both the executive and legislative branches prepare revenue forecasts and revenue estimates. In the executive branch, revenue forecasts and estimates are prepared by the Office of Tax Analysis (OTA)—in the Treasury Department’s Office of Tax Policy—for the Office of Management and Budget, the agency responsible for all executive branch budgetary matters.

In Congress, the Congressional Budget Office (CBO) prepares the baseline revenue forecast and estimates (“scores”) the revenue impacts of specific spending proposals. The House and Senate Budget Committees use CBO’s revenue forecasts to develop both their annual budget resolutions and their directives to other congressional committees. The Joint Committee on Taxation (JCT) staff is the official

Congressional “scorekeeper” in determining the revenue impact of proposed tax law changes. Congress will not consider tax law change legislation unless it is accompanied by a JCT revenue estimate.

State Governments

Among the states, the institutional responsibility for revenue forecasting varies. According to the National Association of State Budget Officers,^[1] in 17 states, the executive branch has the primary responsibility for developing the official state revenue forecast; in 22 states, a consensus process is used to arrive at the forecast. The consensus group generally consists of representatives of the executive and legislative branches; private sector and university representatives may also join the group. Many studies have indicated that consensus forecasting is quite advantageous in producing accurate forecasts.^[2] In the states, revenue estimates are presented to the legislature as fiscal notes appended to tax bills. The notes may be prepared by the executive agency responsible for revenue forecasts or by other agencies in the executive branch. In some states, legislative staff members may also prepare revenue estimates.

Local Governments

Information about institutional responsibilities for revenue forecasting in the more than 87,000 substate governments in the United States—of which close to 20,000 are classified by the U.S. Census as municipal governments—is primarily anecdotal. It indicates that the executive branch of government is generally responsible for the forecasts. However, in large cities such as New York, legislative staff may also prepare forecasts, and in some municipalities, academics or other consultants from outside the government may provide them.

REVENUE ESTIMATION AND FORECASTING METHODS

The four primary approaches currently used by governments to forecast revenues are 1) qualitative methods; 2) time-series methods; 3) econometric modeling; and 4) microsimulation modeling. Functional forms and examples of approaches 2 through 4 are shown in the appendix at the end of this article.

Qualitative Methods

Qualitative (or subjective) methods to predict revenues rely on expert judgment and opinions. Although few governmental units depend solely on judgment to forecast or estimate revenues, it is often used to inform and modify the results of more formal quantitative forecasting methods. A common application of the subjective approach is consensus forecasting in which information from several forecasts is used to arrive at a final revenue projection.

Time-Series Methods

In time-series methods, data on revenues in a past year or years are used to forecast revenues for the upcoming year(s). There are four general approaches to time series forecasting: 1) simple trend analysis; 2) the autoregressive approach; 3) the mixed technique approach; and 4) the approach that uses data on seasonal fluctuations of a revenue source to predict and adjust current year revenues. The first three methods are used to forecast revenues for the upcoming year(s); the fourth approach is used to predict revenues within a budget year based on collection data for the first few months of the year.

The simplest type of trend forecasting assumes that revenues in the forecast year will grow by the same absolute amount as in the past year, or by the same percent as in the past year (appendix, Eqs. 1 and Eqs. 2). Other trend forecasts assume that revenues in the forecast year will grow at the same average percent as in the past several years, or by the same average amount as in the past several years (appendix, 3 and Eq. 4). The latter method is equivalent to estimating a trend line.

More sophisticated time-series approaches to revenue forecasting use autoregressive techniques in which the prediction is generated by a weighted average of past observations going back “n” periods with a random disturbance term for the current period (appendix, 5). Many autoregressive models use regression techniques that incorporate corrections for autocorrelation of residuals and/or for moving average processes into the models. The Box-Jenkins ARIMA (autoregressive integrated moving average)

model is an example of this approach. Trend analysis may be modified to take rate or rule changes into account (appendix, Eq. 6). The historical revenue data can be adjusted to take the change into account, or if a time trend regression is used, the change can be explicitly included.

The main advantage of time-series models is their limited data requirements relative to other forecasting approaches (e.g., econometrics, microsimulation) because they require only a data series of the revenue being forecast. However, time-series models do not incorporate changes in the economic or demographic base underlying the tax structure, and this is seen as their primary disadvantage.

Econometric Models

An econometric model is essentially a mathematical representation of an economic phenomenon. The econometric approach to revenue forecasting differs from time-series analysis in that the former is based on assumed relationships among the variables rather than just on changes over time. An econometric model may consist of a single equation, a set of equations that are solved recursively, or a set of equations that are solved simultaneously. In a recursive model, forecast data for the independent variables are fed into the system; there is no feedback among the forecasts of the dependent variables; in a simultaneous model, there is feedback among the forecasts.

The simplest econometric model that might be used to forecast revenues posits that tax revenues in time period “t” depend on the tax base in “t” and the tax rate in “t.” The model involves only one equation (appendix, Eq. 7), and both the tax rate and the tax base are exogenous to the model. In a recursive system, there would be at least one equation besides the revenue equation, and the second equation would be used to forecast the tax base. There would be no feedback from the tax revenue to the tax base variables. In a simultaneous model, there would be feedback between the tax and economic variables. Although this type of system is more complex both to estimate and to forecast, it provides a more realistic look at the tax system than either a trend model or a recursive model.

Numerous issues must be resolved when using econometric modeling techniques, including forecasting the underlying economic variables included in the model, solving the liability/collection timing problem, defining the tax base, and adjusting for legislative changes during the modeling period.

The first issue relates to the fact that econometric revenue forecasting models are driven by the variables fed into them. Predicting these variables is especially difficult in uncertain economic times because many

are sensitive to, and reflect, rapidly changing macro-economic conditions. For example, among the macro-economic variables that feed into federal revenue forecasting models are wages and salaries, employment, and several business condition indicators, such as corporate profits—all variables that are highly sensitive to a changing environment. Subnational revenue models incorporate these national indicators, as well as variables that relate to the state and local economies, making them even more vulnerable to changing conditions. To the extent that the underlying forecast of the economic variables errs, so too will the revenue forecast.

A second issue in using econometric models is the underlying relationship between economic activity and tax collections. In econometric models, relationships are generally posited between economic activity and tax liability (i.e., how much tax is owed relative to the level of economic activity). However, economic activity and tax liability in a given year do not necessarily translate into tax collections for that year. Current tax year liability may reflect economic activity in the past year and/or accounting practices.

Connected to the liability-collection problem is the timing of collections and the proper temporal relationship between economic variables and collections. For example, when building an econometric model to forecast business taxes, there are a number of factors that confound the results. Corporations may not use the same fiscal year as the tax collecting entity. Corporations also have the ability to extend payment periods so that their economic activity in a given year may not relate to their tax payment in that year. These same factors may apply to personal income taxes although to a lesser extent.

A third issue in econometric revenue forecasting results from the lack of appropriate data to measure the tax base as defined in tax law. This is especially difficult for state and local governments. For example, lack of appropriate data is a major difficulty in forecasting sales tax revenues because the federal government stopped publishing regional retail sales data (usually a close approximation to the sales tax base) in 1996. Since then, it has been necessary to estimate state retail sales data prior to specifying the sales tax revenue forecasting equation. One way to do this is to “share” national retail sales data down to the state level. However, this methodology will produce inaccurate state sales data if state sales patterns differ widely from national patterns.

A fourth issue relates to changes in tax rates. The basic econometric forecasting model includes tax rate(s) and the tax base. If the rate remains stable, it can be excluded for purposes of revenue forecasting. However, if the model is used for estimating the impact on revenue caused by changes in tax rates (or tax rules), an assumption must be made

about how the change in the rate will affect collections. This will depend, to some degree, on the elasticity of the tax with respect to rate changes. Non-“rate” legislation such as caps, minimum taxes, and tax holidays are also considered, usually through dummy or other variables.

Microsimulation Models

The microsimulation model uses data from a probability sample of computerized individual taxpayer returns (or averages of individual taxpayer returns within tax brackets), along with a “tax calculator” to predict taxpayer behavior. This “tax calculator” is basically a computer program that manipulates the sample of tax returns using a set of input parameters that define the tax laws. For example, an equation to predict the income tax for a taxpayer in a specific tax bracket would be specified as follows:

$$\begin{aligned} \text{Tax revenue}(i) &= \text{tax rate}(i) \\ &\quad \times (\text{income} - \text{exemptions} \\ &\quad - \text{deductions}) \end{aligned}$$

where i is the tax bracket. There would be separate equations used for each tax bracket. The results for individual taxpayers in each tax bracket in the sample would then be weighted and applied to the entire set of taxpayers with the summation constituting the forecast of baseline tax revenues for the upcoming budget year. Unlike an econometric model, a microsimulation model is not estimated from historical data using a statistical method [e.g., ordinary least squares (OLS)]; thus, equations in microsimulation models do not include error terms.

Using the microsimulation model to estimate the impact of specific tax law changes can be accomplished in three ways: by changing the tax parameters, by changing the coding of the tax calculator, or by changing both. The tax calculator is changed by deleting certain code lines, by adding new code lines, or by doing both.

Some of the issues to be addressed when using a microsimulation model are similar to those that must be addressed in using econometric models [e.g., the temporal relationship between taxpayer liability and collections]. Taxpayers may not necessarily pay their taxes in the year for which the simulation is run. Other issues are unique to the microsimulation model itself. For example, the selection of the sample and the sample size will affect the outcome of the model. The use of large samples is expensive and time consuming, but reducing the sample size may reduce the reliability and validity of the results. The microfile must also be kept up to date with respect to the taxpayer base and must be modified to incorporate changes in the tax law.

Multiple Methods

Each of the four principal approaches to revenue forecasting and estimation may be (and is) used separately. However, given the limitations associated with each approach, many governments use multiple methods to forecast and estimate revenue more accurately. For example, New York City uses multiple methods to forecast its personal income tax revenues and a microsimulation model to forecast total tax liability. Withholding, estimated payments, and settlement payments are forecast using historical relationships, and estimated payments are forecast using an econometric model.

SELECTION OF FORECASTING AND ESTIMATION METHODOLOGIES

Federal Government

The OTA in the executive branch, and the CBO and the JCT in Congress, rely primarily on the Individual Income Tax Simulation Model (a microsimulation model) and the Corporate Tax Model (an econometric model) for revenue forecasting and estimation. When these models are not appropriate, others models such as the Treasury's Depreciation Model, as well as models for the estate tax and the foreign tax credit, are used.

The OTA's counterparts at the CBO and the JCT use similar models and estimating conventions. Their forecasts and estimates will, however, differ from those of the OTA to the extent that their underlying macroeconomic forecasts differ. The CBO's economic forecasts serve as the basis for the revenue estimates in the Congressional budget resolution; the CEA's macroeconomic forecasts provide the basis for the revenue forecasts in the President's budget proposals. When the forecasts differ, Congress can accept either because there is no formal mechanism for reconciliation.

Regarding estimation of specific tax law changes, during congressional consideration of tax legislation, the JTC provides the official revenue estimates. However, the executive branch may rely on Treasury estimates in deciding whether to support or oppose a particular proposal. Treasury estimates, when they differ from the JTC estimates, are generally not made public during the markup, but there have been situations when the OTA's numbers have been released.

State Governments

States use various methods to forecast revenues, with close to 40% relying on some type of consensus to make their final revenue forecasts.^[3] Time-series

analysis is generally used to forecast revenue for "non-economic" taxes, taxes whose collections are relatively stable, or taxes whose collections have grown steadily over time. Time-series analysis may also be used to forecast taxes for which there are no rate or rule changes in the forecast period. Where rate or rule changes have occurred, trend analysis may be used if the historical revenue data are adjusted to take the change into account. If a time trend regression is used, the change can be explicitly included.

In 1980, 10 states used complex econometric models for revenue forecasting and revenue estimation.^[4] By 1996, that number had increased to 34, primarily due to the availability of microcomputers that are capable of performing complex econometric equations. At least two-thirds of the states use econometric modeling, microsimulation, and regression analysis, or some combination thereof. Most states use three or four of these methods in some combination to forecast revenues. The methodologies that states use for revenue estimation are generally quite similar to those that they use for revenue forecasting.

Local Governments

Prior to 1999, there were no data available on the revenue forecasting methods used by cities. In 1999, the National League of Cities (NLC) included its first-ever question on revenue forecasting approaches in its annual survey of the fiscal conditions of U.S. cities.^{[5]a} The survey revealed that the predominant forecasting approach that cities use depends on the tax. For the property tax—the main tax revenue source for cities—46% of cities reported that they use only judgment to forecast revenues.

For the sales tax—the second most important tax revenue source for cities—56% of cities reported using only trend analysis to forecast revenues, whereas 21% said that they rely solely on judgment. For the income tax—the third major source of tax dollars for cities—45% reported using only judgment to forecast revenues, whereas 21% said that they relied solely on trend analysis. Local government reliance on subjective approaches for all taxes is not surprising given the paucity of data for local governments. In fact, some cities that have experimented with an econometric approach abandoned it primarily due to the unavailability of data.

^aThe NLC mailed questionnaires to 1056 U.S. cities, including those with populations greater than 50,000 and a random sample of 520 cities with populations between 10,000 and 50,000. The survey asked which of seven revenue-forecasting methodologies they used to forecast tax revenues. The choices were judgment, consensus, trend analysis, time-series analysis, econometrics, microsimulation, and other.

ERRORS IN FORECASTING

Because forecasts are made within a climate of uncertainty and are based on assumptions regarding this uncertainty, there is always the possibility of making a forecasting error (i.e., of under- or overestimating revenues). The magnitude of this error can be determined by measuring forecast bias and forecast accuracy.

Forecast Bias

Forecast bias is the extent to which the forecast differs from actual revenues. The accuracy of a forecast is the degree to which forecast values are narrowly dispersed around actual outcomes. The measure for bias most widely used is the mean error of the forecast that will equal zero over time if there is no bias. This measure is easy to calculate, but may be misleading because the mean error of two forecasts could be identical if, for example, one had small errors and the other had large, balancing errors. Other measures for bias include the calculation of a track ratio that keeps a running total of forecast errors divided by the absolute value of the average error. If the absolute value of this ratio exceeds a predetermined positive number, the model is biased. A third measure used to test for forecast bias is based on linear regression analysis of forecast vs. actual values.

Forecast Accuracy

Accuracy, the primary criterion for judging the performance of a forecast, will more clearly reflect forecasting performance than will the mean error. Two of the most commonly used accuracy measures are the mean absolute error of a forecast and the root mean square error. The mean absolute error is the average of the absolute difference between the actual and predicted values of the forecast over several time periods. The root mean square error is the square root of the average of the sum of the squared differences between the actual values and the forecasted values.

For all levels of government, the size of the forecast error tends to be larger when the economy is unstable than during periods of economic stability and is generally greatest at turning points. Among the states, most studies have found that revenues tend to be underestimated, thus providing a “cushion” for unforeseen economic events and/or expenditure demands.^[6] Research has also indicated that revenue forecast errors in states with a split government (where the leadership in the executive branch, senate, and house are not of the same party) are likely to be larger than errors made in states with a unified government (in

which the leadership in all branches is from the same political party).

Among local governments, the limited information available indicates that revenue underestimation is persistent and substantial.^[7] Results from the NLC’s annual survey provide corroboration of revenue underestimation by local governments. From 1987 to 1996, the approximately 300 governments responding to the NLC survey underestimated budgeted revenue changes in all years, except 1990 and 1991.

ISSUES IN PREDICTING REVENUES

Several problems associated with specific revenue forecasting and estimation techniques have already been discussed. The issues summarized below are more general and, except for the first—the political climate—relate to revenue estimation rather than to revenue forecasting.

Political Climate

There is a rather substantial body of literature on the impact of politics on public budgeting.^b Much less empirical research has been conducted on how politics affects revenue forecasting and estimation. Anecdotal evidence, however, suggests that at all levels of government revenue forecasting and estimation are subject to political considerations, especially with regard to the assumptions made in the underlying economic forecasts.

Indirect and Inducted Effects of Tax Law Changes

The direct impact of a proposed tax law change is what is generally considered in “scoring” tax law changes; rarely are the induced and/or indirect effects of proposed changes included due, primarily, to the complications involved in their estimation.^c At the present time, neither the CBO, the JCT, nor the OTA incorporate indirect/induced effects in their revenue estimates. Among the states, only Massachusetts regularly incorporates indirect and/or inducted effects into its revenue estimation process, and California requires that feedback effects be considered if the tax

^bIrene Rubin summarizes much of this literature in Ref. [8].

^cThere are four major approaches to categorizing these direct and indirect effects: 1) as partial equilibrium or general equilibrium effects; 2) as primary, secondary, and tertiary effects; 3) as microeconomic and macroeconomic effects; and 4) as static and dynamic effects. Most discussion about behavioral assumptions that has taken place in recent years uses the static–dynamic dichotomy, with dynamic effects sometimes referred to as “feedback” effects.

bill is over a specified amount. There is no empirical evidence available suggesting that local governments systemically include anything other than the direct effects of tax law changes in their revenue estimates.

Interaction Among Multiple Tax Rule Changes

Another controversial issue in revenue estimation concerns “stacking,” or the order in which tax law changes are entered into the estimate. For example, the 1986 Federal Tax Reform Act reduced marginal tax rates and broadened the tax base. When estimating the impact of the legislation, the OTA stacked base broadeners first and then rate cuts. Accordingly, the estimates for proposals to narrow the number and level of exclusions or deductions assumed that the existing marginal tax rates would apply to the broadened defined base. The JCT, in contrast, stacked the changes in marginal tax rates first and base broadeners second because most amendments to the tax code were to change tax rates rather than the tax base. Stacking the rate reduction first resulted in a lower revenue estimate than stacking the broadening first. There is no “correct” order in which to enter the proposed changes, but the selection may affect the revenue estimate.

Time Horizon

Still another controversial issue in revenue estimation relates to the time horizon used to calculate the budget impact of the estimation. On the federal level, revenue estimates are subject to the same 5-year time horizon as are all other budget items. This raises the issue of how to “score” changes in tax collections that will result from proposed tax law changes. Scoring is defined as the way in which budgetary actions, including those related to tax rule changes, are tracked. For example, suppose there is a proposed federal tax rule change that would exempt businesses from the corporate income tax starting in year six, if they paid an additional \$50,000 in taxes for years one through five. In years one through five, there would be an increase in revenue resulting from the tax rule; in year six and thereafter, revenues would fall. Because of the 5-year time horizon, the change in tax collections would be scored as a gain, and there would be no scoring for the loss in the later years.

An Intergovernmental Issue

If the federal tax rate structure changes, state and local government tax systems are not affected. However,

changes in the federal tax base may have a considerable impact on state and local taxes if they are “tied” to the federal structure (e.g., if the first entry on their tax form is federal taxable income). For example, when the federal government broadened the individual income tax base in 1986, states tied to the federal structure saw their tax bases broaden and would have experienced what was referred to as a “windfall” had they done nothing to prevent the pass-through. States with relatively high tax rates, such as New York, saw this windfall, not as a benefit, but as a threat to their already unfavorable position vis-à-vis states with lower tax rates. Federal government tax policy experts do not necessarily consider the impacts of such changes on lower levels of government.

APPENDIX A

Illustrations of Time-Series Analysis Equations Used in Revenue Forecasting and Estimation

Simple Trend Analysis

$$\text{Revenue}_t = \text{revenue}_{t-1} + (\text{revenue}_{t-1} - \text{revenue}_{t-2}) \quad (1)$$

revenue grows by the same amount as in the previous year.

$$\text{Revenue}_t = \text{revenue}_{t-1} \times (\text{revenue}_{t-1} / \text{revenue}_{t-2}) \quad (2)$$

revenue grows by the same percent as in the previous year.

$$\text{Revenue}_t = \text{revenue}_{t-1} \times \text{average}[(\text{revenue}_{t-1} / \text{revenue}_{t-2}), \dots, \text{revenue}_{t-n+1} / \text{revenue}_{t-n}] \quad (3)$$

revenue grows by the same average percent as in the previous several years.

$$\text{Revenue}_t = f(\text{time}) \quad (4)$$

revenue grows by the same average amount as in the previous several years. This is equivalent to estimating a trend line and using it to forecast with.

$$\begin{aligned} \text{Revenue}_t &= a + a_1 * \text{revenue}_{t-1} + a_2 \\ &\times \text{revenue}_{t-2} + a_3 \\ &\times \text{revenue}_{t-3} \dots + a_n \\ &\times \text{revenue}_{t-n} + e_t \end{aligned} \quad (5)$$

revenue is estimated using an autoregressive model that goes out for n periods and includes an error term.

$$\text{Revenue}_t = f(\text{time}, \text{tax rate}_t) \quad (6)$$

This is a modification of Eq. 4 to take changes in the tax rate into account.

APPENDIX B

Illustrations of Econometric Models Used in Revenue Forecasting and Estimation

Illustration of the simplest econometric model

$$\text{Revenue}_t = f(\text{tax base}_t, \text{tax rate}_t) \quad (7)$$

This equation says that tax revenues in time period t depend on the tax base in t and the tax rate in t .

An example of the simplest model used to forecast the Personal Income Tax

$$\begin{aligned} \text{Personal income tax revenue}_t \\ = \alpha + \beta * \text{personal income}_t \\ + \theta * \text{personal income tax rate}_t + \varepsilon \end{aligned} \quad (8)$$

α , β , and θ are estimated coefficients, and ε is the error term. The tax rate and personal income forecasts are exogenous to the model.

An example of a recursive model used to forecast the Personal Income Tax

$$\begin{aligned} \text{Personal income tax revenue}_t \\ = \alpha + \beta * \text{personal income}_t \\ + \theta * \text{personal income tax rate}_t + \varepsilon \end{aligned} \quad (9)$$

$$\begin{aligned} \text{Personal income}_t = a + b * \text{employment}_t \\ + c * \text{consumer price index}_t + e \end{aligned} \quad (10)$$

In addition to Eq. 7, there would be at least one other equation—that used to forecast personal income—but there would be no feedback from the tax revenue to income.

An example of a simultaneous model used to forecast the Personal Income Tax

$$\begin{aligned} \text{Personal income tax revenue} \\ = f(\text{personal income}, \text{personal income tax rate}) \end{aligned} \quad (11)$$

$$\begin{aligned} \text{Personal income} = f\left(\sum \text{wage rates}_i \right. \\ \left. \times \text{employment}_i\right) \end{aligned} \quad (12)$$

$$\text{Employment}_{\text{gov't}} = f\left(\sum \text{revenues}_t\right) \quad (13)$$

Personal income tax revenue Eq. 11 is a function of personal income Eq. 12 that, in turn, depends on employment Eq. 13. One employment sector is government employment; it depends, to some extent, on the size of tax collections. Thus, assuming positive relationships among revenues, income, and employment, if the tax rate is increased, revenues rise, which leads to an increase in government employment. This, in turn, results in growth in total wages and personal income, which leads to further increases in personal income tax revenues.

APPENDIX C

Illustration of a Microsimulation Model using the Personal Income Tax

$$\begin{aligned} \text{Average taxable income}_i = (\text{gross income}_i \\ - \text{deductions}_i - \text{exemptions}_i) / \text{taxpayers}_i \end{aligned} \quad (14)$$

where Exemptions_i = value of a personal exemption $\times$ average number of exemptions $_i \times$ taxpayers $_i$, and deductions_i = average deductions $_i \times$ taxpayers $_i$

$$\begin{aligned} \text{Avg. tax}_i = \text{tax base}_i + \text{tax rate}_i \\ \times (\text{average taxable income}_i \\ - \text{lower income bound}_i) \end{aligned} \quad (15)$$

$$\text{Tax liability}_i = \text{average tax}_i \times \text{taxpayers}_i \quad (16)$$

$$\text{Total tax liability} = \sum (\text{tax liability}_i) \quad (17)$$

In this model, there are three income classes, with corresponding tax bases, tax rates, and income bounds. When changes are made in the tax rate structure, or in deductions, exemptions, or credits, the effects on each income class and tax bracket (as well as on total

liabilities) can be predicted. The model can be used to forecast tax liability by income class, as well as to estimate the impact of tax law changes.

Risk Management

David L. Baker

School of Public Affairs, Arizona State University, Tempe, Arizona, U.S.A.

INTRODUCTION

Public agencies operate in a risky environment. Risk relates to the chance of injury, damage, or loss.^[1] It represents a set of circumstances in which multiple outcomes are possible and the probability of each possible outcome can be estimated.^[2] Losses affect the human, financial, physical, and natural resources under the care of a public agency.^[3] Risk management seeks to conserve and to protect public resources from accidental loss. It proactively mitigates governmental risk through awareness, avoidance, assessment, containment, funding, and management oversight.

The following review discusses risks and defines exposures, perils, and hazards. It explicates six primary risk management concepts (risk awareness, exposure avoidance, risk assessment, risk containment, risk funding, and risk management). After highlighting macrotreatment and microtreatment strategies, common elements of governmental risk containment programs are described and the manners in which they minimize loss are examined. The review outlines the major tasks of risk management administration and introduces the notion of pervasive risk management. Following an appraisal of the organizational benefits arising from risk management, the review concludes with an overall summary of the topic.

RISKS, EXPOSURES, PERILS, AND HAZARDS

Two primary types of risk may be distinguished: speculative risk and pure risk. Speculative risk refers to situations where both loss and gain may occur. Pure risk involves unexpected loss without the opportunity of some gain. Public agency risk management deals with pure risk.

An understanding of exposures, perils, and hazards provides a common framework for analyzing pure risks.^[1] Exposures have to do with risk circumstances that can result in a loss. It refers to vulnerabilities resulting from a public agency's existence and its operation. There is no exposure if there is no likelihood of loss. Perils are defined as the actual causes of loss.^[4] For example, perils consist of death, injury, natural catastrophes, litigation, and illegal activity. Hazards boost the probability and/or severity of loss. Actions or

conditions create hazards. For example, faulty brakes on school buses are a hazard that increases the likelihood of the peril of injury, property damage, and litigation.

Risk management seeks to reduce or eliminate losses by reducing hazards. Consequently, it is useful to evaluate hazards by segregating them into three categories: physical, moral, and morale (or behavioral) hazards.^[1,4] Physical hazards are defined as conditions that increase the probability of loss. For instance, the absence of secure exterior doors on a public building constitutes a physical hazard. Moral hazards consist of dishonest behavior by individuals, either observed or unobserved, that affects the likelihood or magnitude of a loss^[5] (e.g., a public employee stealing gasoline from a public agency for the employee's personal vehicle). Morale hazard comes from personal carelessness. An employee recklessly driving an agency's vehicle denotes an example of morale hazard. Within this framework of understanding, the review now turns to explaining the core concepts of risk management.

RISK MANAGEMENT CONCEPTS

Six risk management concepts capture the underpinnings of a comprehensive risk management program for governmental entities. First, "risk awareness" concerns identification of public agency resources that could be affected in unintended, adverse ways and to the detriment of the public interest. Resources face natural events (e.g., monsoons, volcanoes, and earthquakes) and human actions (e.g., terrorism, fires, and lawsuits) with serious consequences for governmental entities. Many exposures present indirect impacts involving expenses to meet essential operations and service responsibilities.^[3] Wide-ranging exposure calls for persistent vigilance to discover and to address public agency risks.

Second, "exposure avoidance" means to avoid or to eliminate a given exposure.^[6] The goal is to remove the likelihood of loss totally. A completely avoided exposure requires no further resource investment for risk containment or risk funding. Consequently, public agencies often attempt exposure avoidance when they first discover vulnerabilities.

Third, after establishing risk awareness and attempting exposure avoidance, “risk assessment” encompasses the gray area between certainty (knowing exactly what will occur) and uncertainty (not knowing what will occur). It confronts Simon’s^[7] “bounded rationality” inasmuch as estimates are made about possible occurrences based on imperfect information.^[8] Risk assessment entails measurement of risk by analyzing past loss frequency and severity probabilities. However, it is forward looking.^[9] Exposures that present the greatest potential impact on an agency command the highest attention. Past loss history primes analysis as a public agency evaluates the extent of possible future losses and the relative likelihood of those losses.

Fourth, “risk containment” follows assessment. It refers to strategies designed to minimize risks and losses. This typically involves policy development and personnel training in many areas including security, safety, environmental protection, and emergency planning.^[3] Risk containment activities require a well-coordinated effort through a designated risk manager. The risk manager functions under a defined system of accountability involving all levels of management, supervision, and front-line employees. Risk management administration is discussed more fully later.

Fifth, some risk losses may be inevitable despite a public agency’s best efforts. As a result, part of a comprehensive risk management program involves “risk funding.” The imperative to preserve a functioning public agency in the face of a significant risk obligates a governmental entity to maintain adequate funds and funding approaches to cover incurred losses. This calls for a mix of tactics designed to shield public assets at the least cost. The “least cost spectrum” ranges from 1) some risk retention by way of self-insurance; 2) risk sharing through some form of multiagency pooling arrangements; 3) the means to borrow from a financial institution; and 4) risk transfer with the purchase of insurance products.^[3] Insurance solutions frequently provide a variety of intermixed methodologies to contain costs. For example, a public agency may be self-insured for the first \$250,000 per incident, have a pooling arrangement for losses involving over \$250,000 but less than \$1.0 million, and purchase insurance to cover losses that exceed \$1.0 million per incident.

Sixth, “risk management” combines governmental risk awareness, exposure avoidance, risk assessment, risk containment, and risk funding through a compelling, coordinated, and communicated effort to protect public assets. This usually involves various levels of policy development, training, staffing, organizing, and ongoing evaluation with periodic public reports to the community served. Conscientious risk management fosters the notion of “pervasive risk management.” This review introduces and explores that subject later.

RISK TREATMENT STRATEGIES

Risk treatment strategies commence with management fundamentals at the macrolevel. After analysis of an agency’s strengths, weaknesses, threats, and opportunities, management initiates a risk management vision. This usually includes a statement of exactly what the agency seeks to accomplish, identification of resource allocations to support the desired accomplishments, measurable outcomes, and timelines for monitoring activities. Periodic performance review should include a regime of internal and external critique.

Moving to the microlevel, risk treatment strategies generally include many implementing measures that flow from macrolevel activities. For example, successful public agency risk treatment strategies require; 1) briefing elected officials and public policy approvals; 2) communicating, coordinating, and educating the organization; 3) discussing and involving staff throughout the organization to identify and assess risk areas; 4) carefully constructing risk management policies; 5) implementing procedures and providing constructive assistance to organizational units in policy applications;^[3] 6) monitoring and evaluating reports to review compliance, tackle problems, measure trends, and exploit emerging opportunities; and 7) periodic external critique through timely audits and review of data from comparable jurisdictions known for outstanding practices and performance.

RISK CONTAINMENT PROGRAM ELEMENTS

Risk containment is a central focus of risk management. It meets the objective of minimizing risks and losses through initiating activities that positively alter the probability that a loss incident occurs. When an incident does happen, the goal is to reduce the severity of the loss and provide a means for recovery. These activities, or program elements, are designed and modified based on specific risk exposure and assessment analysis. Common elements of governmental risk containment programs include the following.

- **Security:** Protecting people, possessions/property, information,^[3] and the means to use information (information and communication technology) from illegal or unauthorized internal and external threats.
- **Personal safety:** Meeting all employee and citizen health and safety regulations,^[3] taking preventative measures, maintaining records of concerns and incidents, and training individuals as needed.
- **Equipment safety:** Developing and enforcing use standards on all equipment to assure safe operations. This may include checking weapons on law

enforcement personnel, needle-stick and lifting protocols in public hospitals, and specialized forklift training in governmental warehouses.

- Emergency preparedness: Developing contingency plans to address natural and environmental disasters as well as human-induced actions. Such preparedness aims to safeguard human, private, and governmental loss.

Beyond these risk containment program elements, there are several techniques designed to minimize loss.^[1] First, loss prevention hunts for ways to avoid harm before something occurs. For example, security guards may serve as a deterrent to theft. Second, loss reduction strives to cut the consequence of a loss. For instance, fire detection alarms and extinguishers may lessen a loss once a fire starts. Third, segregation relates to tactics taken to trim down potential harm. This is illustrated in the practice of insisting that several elected officials attending a conference use more than one aircraft for transportation. Fourth, and finally, duplication or redundancy protects an agency by assuring the availability of a replacement asset in critical situations should the primary asset be lost or malfunction. A case in point would be the provision for a backup generator to maintain computer services to law enforcement and fire suppression personnel during an electrical power shortage.

RISK MANAGEMENT ADMINISTRATION

Risk management programs require continuous direction and careful attention.^[3] The staffing component dedicated to the effort varies depending on organizational size, complexity, and available resources. Effective programs administratively focus on the following activities.^[1]

- Developing the overall mission and adaptive strategies, including periodic elected official briefings, generation of written policies, and constant performance monitoring and improvement.
- Defining responsibilities and organizing resources for risk awareness, exposure avoidance, risk assessment, risk containment, risk funding, and risk management.
- Communicating throughout the organization and to the public about the overall agency's challenges, objectives, and progress.

The job of risk manager requires a multistep process. The designated individual works as staff to the chief administrative officer in developing an organizational vision, mission, and objectives for the risk management effort. A comprehensive program is developed

and implemented to contain and to manage exposures. Internal self-audit as well as external evaluation hone practices and refine strategies while identifying areas for continuous improvement and modification.

PERVASIVE RISK MANAGEMENT

Risk management requires deliberate attention throughout governmental activities. This does not mean that risk adversity should stifle governance and delivery of services with creativity crushing inertia. It does suggest that risk management needs to be addressed as part of everyday governmental activities. The notion of "pervasive risk management" calls for integrating macrorisk and microrisk management thinking into the daily activities of government. It brings systems thinking to bear on risk management holistically. Proactive problem solving emanates from examining the context of the system where the concerns arise.^[10] Conserving and protecting public agency resources should not be an afterthought.

Public agencies need to push risk containment program elements back into program planning and strategic thinking at the earliest point possible to achieve risk management at the lowest cost. The pervasive risk management notion requires that the classical functions of planning, organizing, staffing, directing, coordinating, reporting, and budgeting^[11] consider all these activities with sensitivity to risk management.

RISK MANAGEMENT BENEFITS

Several public agency benefits arise from risk management activities.^[1,9,12] The more compelling involve; 1) control of insurance costs; 2) enhanced communication, coordination, and record-keeping; 3) active case, or claims, management; 4) finely tuned risk sensitivity and training to curb injuries and claim expenses; 5) more sharply focused insurance decisions; 6) heighten security for citizens, employees, and public agency assets; 7) minimal operational disruptions; 8) immediate resources to address some losses and funding strategies to address larger losses; and 9) more proactive administrative leadership and an enhanced organizational culture to support it. Individually and collectively, these benefits boost the effectiveness of a public agency while conserving and protecting public resources.

CONCLUSION

All public agencies function with some level of risk.^[13] Risk management seeks to conserve and to protect

public resources from loss. It does this through a vigilant campaign of awareness, exposure avoidance, assessment, containment, funding, and overall management. There are macrorisk and microrisk treatment strategies, and public agencies are well served through implementing effective security, personal safety, equipment safety, and emergency preparedness programs. Risk management administration critically focuses on risk management leadership, responsibilities, resources, and communications. Execution of a comprehensive effort involves the notion of pervasive risk management where systems' thinking about risk management permeates the organization. The many benefits of a sound risk management program boost the effectiveness of a public agency while guarding public resources.

Risk Pools

Peter C. Young

Graduate School of Business, University of St. Thomas, Minneapolis, Minnesota, U.S.A.

INTRODUCTION

The emergence of pooling may be one of the more significant developments in the field of American public sector risk management (pools also exist in Japan, Australia, and a handful of other countries). Pools developed in the United States in response to two episodes of insurance unavailability and unaffordability in the 1970s and 1980s. Since that time, they have grown in size and number to a point where they are a dominant provider of risk financing for local governments. Further, they have had a profound impact on the practice of risk management in, particularly, small local authorities.

This article introduces both the concept and practice of pooling. After briefly discussing the concept of pooling, a history of pooling is presented, followed by a description of pool forms and functions. The article concludes with an overview of practical issues, challenges, and problems facing pools today.

POOLING AS A RISK MANAGEMENT TOOL

The idea of pooling is rather simple in one sense, and quite technically complex in another. In the simple sense, pooling is a means of protection; if a group of individuals pool their time and efforts, they can provide for a common cause that is more effective than could be provided through individual initiative. This is an example of *resource* pooling, which commonly has the goal of extending capabilities.

In the more complex sense, the pooling of *risks*, although offering some of the capacity-expanding features that resource pooling provides, focuses more on the matter of risk or uncertainty reduction. Pooling can improve predictability, stabilize budgeting and forecasting, and reduce fear and worry. The subtle distinctions between risk and resource pooling are not always visible to the naked eye, and in fact, they overlap to a certain degree. However, readers need to recognize that two distinct things can occur in pooling: 1) the pool participants can achieve more than is possible as individuals and 2) uncertainty and risk can be reduced.

Risk pooling almost invariably is a means of financing risk and in this way is related to the concept of

pooling in insurance. Relying on actuarial principles, risk financing pools can structure financing arrangements to provide a stable flow of funds into the pool—funds that are adequate to cover the sporadic outflows that occur due to losses.

Resource pooling tends to apply to a broader range of risk management (indeed, general management) activities where capacity enhancement is more critical than is risk reduction. Mutual aid agreements, group purchase programs (for school books, insurance, equipment, and machinery), and regional cooperatives all represent activities that seek benefit from enhancing capabilities, not necessarily from reducing uncertainty.

Interestingly, risk pools mainly began as risk financing pools, but have been evolving into risk management pools. Or, to put it in the language of the preceding discussion, pools initially focused on risk pooling, but have begun to broaden their scope of activity into resource pooling.^[1]

HISTORY OF RISK POOLING IN THE UNITED STATES

Since 1970, state and local governments have experienced two “insurance crises,” the first occurring in the mid- to late 1970s and the second in the mid-1980s. These downturns in the insurance market were the result of cyclical market problems, the state of the economy preceding each episode, insurance industry management practices, and inherent insurance pricing problems. The basic riskiness (or perceived riskiness) of the insured—state and local governments—also was a factor. The result has been a 25-year period of time in which state and local governments have been able to afford commercial insurance (particularly liability and workers’ compensation insurance) only intermittently, if insurance has been available at all.^[2]

In response to this problem, local governments, government associations, and even state governments acted to create alternative risk financing mechanisms to provide coverage for local governments. These mechanisms, commonly referred to as self-insurance pools, enabled local governments within a state to pool together risks and resources to finance the costs of fortuitous losses. Initially, the pools provided mainly liability and workers’ compensation coverage for

members. However, pools today provide a wide range of coverages, ranging from property coverage to employee benefits.

A 1988 study of pools found that approximately 200 (see discussion below on counting pools) public risk financing pools operated in the United States.^[3] Those pools, with an estimated aggregate membership of between 15,000 and 20,000 entities, were found in almost all regions of the country—although over one-half of the pools were located in California. Almost all pools were found to be homogeneous as to membership; that is, school districts pooled with school districts, counties with counties, and so on. The pools also tended to be homogeneous as to member population/size. Almost all pool participants could be characterized as small local governments. The pools themselves, however, varied widely in terms of size; the smallest pools reported three to five participating governments, with the largest reporting 1100 to 1300 members.

In 1994, a follow-up study was conducted to find out the degree to which the pooling environment had changed.^[4] It had, dramatically. The findings indicated that there were at least 400 pools in operation, and that these pools had an aggregate membership of 30,000 to 35,000 local entities. Pools still remained the preserve of small local authorities, with membership consisting largely of entities in communities with populations under 10,000.

By 1994, pooling had spread throughout the United States and California no longer dominated the pooling world in quite the same way. Over one-half of the pools were sponsored by associations (e.g., leagues of cities, counties, school board associations), and the estimated aggregate contributions were believed to be about \$5.5 billion.

Since 1994, evidence suggests that pool growth has moderated. No updating studies have been undertaken as of 2001, but experienced observers suggest that the number of pools has plateaued just above 500. (There is some controversy about how pools are counted because some pools are “clusters” of funds—for instance, a pool consisting of four individual coverage programs with segregated funds could be identified as one pool or four pools. Using clusters as the basis for counting, there probably are about 250 pools).^[5] The reasons for the slow down in expansion is identified below.

Looking back on the history of pooling since 1970, we can say that pooling is a significant public sector innovation. Some analysts believe that pooling engages nearly one-half of the local governments in the United States, and may have become a \$6 to \$7 billion “industry.” Given this significance, it is important to look more fully at pooling forms, functions, and practices.

POOLING TODAY

Legal Forms of Organization

Risk financing pools were difficult, if not impossible, to form until state legislatures took steps to permit a general exemption to the prohibitions on the comingling of public funds. The state of California established a “joint powers authority” provision in its state statutes, which had an immediate and profound effect—by the late 1980s, over one-half of the 200 pools in existence were in California. Because this was the case, the joint powers authority model (or sometimes an interlocal cooperation act) was adopted by many other states.

Consequently, nearly 60% of all pools are organized as joint powers or interlocal cooperation act agreements. Other approaches are used, however. Over 20% of pools are legally organized as non-profit trusts, whereas another 5% assume a corporate form. A few are legally constituted as mutual or reciprocal insurance companies, or as risk retention groups.

Sponsorship

Related to the matter of legal form is the question of “sponsorship” or pool ownership. About one-third of all pools are organized by a sponsoring association, such as a state municipal league or association of counties. Of the non-association pools, the majority were formed by voluntary collaboration among member entities, although there also are instances of specific individuals or organizations (e.g., a local insurance agent) serving as a catalyst for pool formation.

Pool Types and Functions

Conceptually, one might imagine that pools could approach the task of risk financing in several different ways. A pool could be organized to do just one thing—say, provide risk financing for workers’ compensation risks. Or a pool could offer several types of coverages; for example, general liability, property coverages, and police officers’ liability protection. Single coverage pools are referred to as “monoline” pools and multiple coverage pools are “multiline.” Due to enabling statute language in many states, some pools offer multiple coverages, but must offer them through distinct and separate pooling arrangements. For instance, a pool management organization might have responsibility for a workers’ compensation pool, employee benefits pool, and a property risk pool. Such arrangements are known as “fleet pools.”

A slightly different way of looking at pooling types is to consider the mechanics of the risk financing arrangements. Most commonly, pools are structured

on a risk-sharing basis, which is to say that they operate more or less like an insurance company. Funds are collected and pooled, and losses are paid out of those pooled funds. The risk sharing may occur on a primary-level basis (all losses, small or big, are financed) or on an excess-level basis (only large losses are financed). Other pools, although admittedly not many, are purely group insurance buying pools. They only pool premium dollars used to purchase commercial coverages for members. Perhaps not surprisingly, many pools are risk financing at the primary level, and insurance buying at the excess loss level (roughly approximating the reinsurance arrangements that insurance companies rely on).

Other pools, although again not many, assume what is called a banking form. They do not commingle funds, but maintain separate accounts for members. They can loan funds to members if losses are high, but they are not risk-sharing arrangements in the conventional sense of the term. Finally, a handful of pools are not involved in risk financing, but provide administrative services to members.

It should be noted that another form of pool has emerged in recent years, the “risk management pool.” This form engages the pool as the risk manager for its member entities. In that capacity the pool not only provides risk financing arrangements, but also provides risk assessment, control, and management services. The risk management pool, in some sense, appears to be an evolutionary stage for pools—meaning that many risk financing pools realized that successful pooling required that efforts be undertaken to manage the underlying risks. It must also be said that the move toward broader risk management services has been somewhat spurred by customer demand and also by competitive pressure (from the commercial insurance industry).

Before departing the subject, a recent development is the emergence of excess pools—really, “pools for pools.” Such pools provide varying forms of large-loss protection for pools in a manner similar to excess insurance and reinsurance. The Schools Excess Liability Fund in California, the County Reinsurance Limited, and the National League of Cities’ National Public Entity Excess program are examples of this new innovation.^[5]

Pool Governance

Almost all pools have a governance structure that is organized around a board of directors/chief executive form of organization. The boards, which typically consist of representatives of pool members, are elected boards about one-half the time and appointed boards in about one-quarter of the cases. Remaining pool boards are partially elected and partially appointed.

The relationship of the board to the pool varies in numerous key ways, but the distinction between sponsored and non-sponsored pools suggests one way in which board/pool relationships may differ. Non-sponsored pool boards derive from the membership and are more or less directly responsive to members. Sponsored pool boards also derive from membership, but may also derive from the sponsoring organization. Frequently, for instance, the chairperson of a pool board is the executive director of the sponsoring organization (a league of cities or an association of counties, for example).

Abstractly, the issue of conflict of interests or purposes arises in a sponsored pool setting. Association interests and member interests (even pool management interests) do not always coincide, and the governance processes by which these conflicts are resolved is not widely known or understood. As just one illustration of this point, risk financing pools rely on the principle of rate and risk relationships—that is, higher risks pay more for coverage than do lower risks. This rate “discrimination” is a convention of pooling, but often associations view pools as a “benefit” of association membership, suggesting that members should not be discriminated against.^[6]

Pool Management

The chief executive reports to the pool board, but otherwise has responsibility for the management of the pooling operation. This includes staff management.

There is a wide degree of variation and size in pool staffs. Research suggests that, on average, pools have a staff of six. However, the largest pools may have a staff of 100, whereas the smallest may have only a single part-time administrator. Size of staff is predicated not only on pools’ size, but also on the degree to which functions are outsourced or kept in-house. Historically, pools have relied heavily on third-party providers to supply services, such as:

1. Claims management
2. Underwriting
3. Loss control
4. Actuarial and financial audit
5. Legal counsel
6. Investment management
7. Banking services
8. Brokerage
9. Management consultancy
10. IT management
11. Sales and marketing

However, as pools have grown in size and experience, there has been a tendency to bring such functions

inside the pool, meaning staff size expands. Increased control or the hope of reduced costs are cited as the primary motivations for such moves. However, there is also some evidence that a few pools are being managed by brokers, agents, or outside management firms—in a sense, pool management has been completely outsourced.

Coverages Provided

There are two ways that one might understand the different coverages provided by pools. First, pools could be sorted out according to the range of coverages offered by individual pools. In this regard, findings would suggest that most pools offer quite limited ranges of coverages. Monoline pools, by definition, offer a single line of coverage—say, workers' compensation. Fleet pools, also by definition, are collections of pools that each offer a single line (or, occasionally, a narrow cluster of lines) of coverage. Even the multiline pools tend to focus on a rather narrow band of related coverages. It is the rare pool that offers an extremely wide assortment of coverages.

Second, one could ask what is the range of coverages offered by the pooling community as a whole, and the answer would be impressively wide ranging. For example, in the 1994 study, all the following lines of coverage were found to be offered by at least one pool:

1. Building and contents
2. Inland marine
3. General liability
4. Auto property and liability
5. Crime
6. Employee dishonesty
7. Workers' compensation
8. Unemployment compensation
9. Boiler and machinery
10. Public official's liability
11. Law enforcement liability
12. Medical malpractice/hospital liability
13. Mass transit property and liability
14. Liquor legal liability
15. Airport liability
16. Umbrella liability
17. Excess loss
18. Reinsurance
19. Pollution
20. Criminal defense reimbursement
21. Land use takings

As a point of reference, the most frequently provided coverages (in order) are general liability, auto property and liability, building and contents, public official's liability, and inland marine and workers' compensation.

Pool Membership

Estimates suggest that 30,000 to 35,000 local authorities participate in pooling; a significant number representing around 40% of all governmental entities in the United States.^[7]

Also pooling is a small government phenomenon. Fully 94% of pool participants are under 10,000 in population. Having noted this, it is also true that many entities with populations up to 100,000 have participated in pooling. So, perhaps it is somewhat more accurate to say that pools have proven useful for local entities with populations up to 100,000, but that, for several reasons, smaller entities have a greater likelihood of participate in pooling.

Pool memberships almost always are homogeneous as to state, member type, and member size. Although some experimentation has begun to occur with interstate arrangements, the authorizing legislation, as well as practical and political considerations, limits most pools to single-state operation. Because homogeneity is such a critical criteria for pooling (simply put, the less alike pooled risks are, the more likely the inequities and aberrations), one should not be surprised to find that most pools consist of similarly sized members of a common entity type.

Surveys show that pool membership in the United States includes municipalities, counties, townships, school districts, and special districts, such as county appraisal districts, housing authorities, municipal utility districts, regional special education consortia, port authorities, hospitals, special services cooperatives, water districts, drainage districts, zoological societies, nutrition councils, river authorities, and, most recently, non-profits such as transit and hospital organizations.

The pools themselves reveal a wide range of sizes with respect to membership numbers. The smallest pools have three to five members, whereas the largest are approaching 4500 members.^[5]

Pool Financial Management

It is estimated that member contributions to pools are approaching \$7 billion. Given such a sizable level of economic activity, it is useful to understand the basic mechanics of pool financial management.

Rate and Premium Development

Historically, pool rates were derived from insurance industry data (the Insurance Services Office, a rating bureau, in particular). This was natural because pools had no past data on which to estimate claims, and also because the consulting actuaries who assisted pools in rate development had knowledge of and access to such

information. Over time, however, pools have demonstrated a strong move away from insurance industry-based pricing, and now rely to a larger degree on their own loss experience.

As a point of reference, insurance premiums consist not just of the expected losses that will be paid, but also of the expenses and overhead charges necessary to administer the insurer. Pool contributions also contain expense loadings, but it is also important to realize that the components are not identical to insurance company expense loadings. The principal differences are: 1) most pools do not have to pay federal or state income taxes; 2) most pools do not have to pay insurance premium taxes; 3) most pools do not have to make participation commitments to state guaranty funds, high-risk pools, or other arrangements mandated by the state insurance commissioner; and 4) most pools do not have to make allowances for agent and broker commissions. These differences are not inconsequential and could, everything else being equal, account for 10% to 20% spread between a pool's premium and a commercial insurance company's premium. The premiums charged to members are payable annually (in over one-half the cases), or monthly, quarterly, or semiannually (in nearly one-half the cases).

Assessments and Refunds

In conventional insurance companies, the premium that is paid is the sum total of the insured's consideration under the contract. However, some cooperative (or "mutual") types of insurers reveal an assessment feature to their pricing scheme, which means that the insurer can require additional contributions to the pool if losses exceed some predetermined level. Assessability may be limited or unlimited.

Most pools are assessable pools (over 8 out of 10); of those assessable pools, nearly 70% have unlimited assessment features.

Refunding, rebating, credits, and dividend distributions are other means by which premiums paid may be adjusted. A majority of pools use one or more of these tools to offset the contribution costs if loss experience is favorable. Another widely used measure is discounting, whereby the pool discounts that initial contribution based on the supposition that the pool will be able to prevent losses from rising to a level that would justify the undiscounted contribution.

Other Financial Management Issues

In 1992, the Governmental Accounting Standards Board (GASB) implemented Statement 10, which serves as a broad directive on pool accounting practices. The GASB 10 (as it is called) is almost universally

adopted as the basis for issuing financial reports today, which has gone a long way toward standardizing pool reporting and is beginning to allow for greater transparency of pooling performance.^[8]

The GASB 10 has not only promoted standardization, but also has naturally had a significant effect on how pools reserve for losses, how they report losses, and on matters related to investment returns, discounting, maintenance of surplus/contingency funds, and other financial issues.

Because most pools are not taxable entities, financial analysis of pooling performance is not influenced by state or federal income tax considerations. This "advantage" over commercial insurance companies is somewhat offset by the restrictions that exist for investment of funds. Although insurance companies are subject to regulatory restrictions with respect to the riskiness of investments, public entity restrictions are even more stringent, and the standards that apply to public sector investment practices apply almost universally to pools.

Finally, a word should be said about alternative risk financing schemes. The phrase "alternative risk financing" used in relation to pooling is rather ironic because pooling is a classic alternative risk financing scheme, when compared with commercial insurance. However, in recent years, methods of financing pools have begun to alter somewhat. Most frequently (and an irony in its own right), pools have begun to purchase more commercial insurance, typically in the form of excess loss and reinsurance coverages. Less frequently seen alternative approaches include debt and banking arrangements, such as letters and lines of credit, bond issues, and finite risk insurance programs.

POOLING: A LOOK AHEAD

Pools now are well into their third decade of existence, and the general evidence suggests that they will continue to be an important presence in the world of public sector risk management. But this is not to say that there are no difficulties or challenges.

Pool administrators naturally argue that their pools are doing better than commercial insurers who operate in the public sector market. Their explanations seem to suggest the heart of the matter for pools. The overriding perception is that pools are more effective than insurance companies because the pool members are the owners and have greater control over the pool than they would over an insurer. In addition, administrators argue that pools understand the public sector better because they are "of the public sector." True proof of pool superiority will ultimately be established through financial performance. To date, no research has been undertaken to explore this issue. Arguably,

the adoption of the GASB 10 will ultimately have the effect of allowing for such analysis, but it has not yet been done.

When looking to the future, pools tend to report concerns about increasing competition from commercial insurers, challenges to maintain positive member relations, and possible legislative or regulatory changes that could adversely effect the ability of pools to operate as they presently do. More generally, many observers are concerned about the future of pooling in light of a re-emergent commercial insurance marketplace. Does the government have a role competing with private business? Although the answer at present seems to be “yes,” analysts agree that the nature of that market-based relationship is not known at the present time. Pooling likely will continue, but there are many unanswered questions that remain.^[9]

One point that should not be overlooked when considering the role/legacy of pooling is their impact on risk management practices in the public sector. At previous points in this entry, the concept of a risk management pool has been cited as both an abstract idea and as a trend in pooling practices. Certainly, an argument can be made that small local authorities can benefit greatly from the introduction of risk management practices, as well as risk financing services. Certainly, it seems that resource pooling can enable such small entities to develop fairly sophisticated practices—well beyond their individual abilities to do so. But is this actually happening?

The answer seems to be “yes.” An investigation of pools today shows that a diversification of risk management services is the most obvious event occurring within the pools. These services range from training and education to the promulgation of manuals, workbooks, risk checklists, and other risk control tools, to political lobbying to state legislatures, to resource pooling, to strategic planning, and a host of services intended to make members better managers of risk.

One innovation, not widely seen, but harkening back to the prepooling era is the circuit-riding risk manager, and some pools have adopted this practice as a way of getting a “ground-level” risk management presence in the member entities.

Regardless of the specific innovations, there is little doubt that pools have introduced risk management into thousands of local authorities that otherwise would not have had such an exposure. Even were pooling to disappear over time, it is likely the imprint of the pooling movement would remain.

Rulemaking

Cornelius M. Kerwin

American University, Washington, District of Columbia, U.S.A.

INTRODUCTION

The official definition of rulemaking found in the Administrative Procedure Act (APA) is admirable in its simplicity, but does little to convey the weight and substance of this most critical element of the American public policy process. The act, at section 551, states that “rulemaking means agency process for formulating, amending, or repealing a rule.”^[1] More instructive is the definition of “rule” that is contained in the subsequent section of the APA: “rule means the whole or part of an agency statement of general or particular applicability and future effect designed to implement, interpret or prescribe law or policy.”^[2] We begin to comprehend the role of rulemaking in governance when we understand this definition grants rulemaking the authority to act on our law with a great range of impact.

RULEMAKING

When implementing law, rules provide nothing more than vehicles to carry the content of statutes to those affected by their provision. Rulemaking in these cases simply builds the conduit. Interpretation of law in a rule or regulation suggests a more substantial effort because it suggests that the language in the legislation is adapted—in some cases stretched and in others contracted—to achieve the intent of the Congress of the United States, in light of the circumstances that the agency perceives in the affected populations or activities. Rulemaking in such instances involves more judgment and knowledge of the external environment than simple implementation. In those cases when agencies prescribe law or policy, they are acting to transform general goals and authority granted them in a Congressional statute into specific requirements. Rule making in these cases fills a largely clean slate, at least considerably more so than when they implement or even interpret. But what is important to note is that in the case of interpretation and most certainly in the case of prescription, the rule-making process effectively supplements or substitutes for the legislative process. This fact is the root of both the genius of rule

making as an instrument of public policy, and the concern in some quarters that its mere existence poses a fundamental threat to the integrity of our democratic system.

DELEGATION OF RULE-MAKING AUTHORITY

Rulemaking enables the existence of a democratic public policy process on an American scale of size and complexity. It is so central and necessary that no less an authority than Kenneth Culp Davis has described a particular form of rulemaking as “one of the greatest inventions of modern government.”^[3] Without the capacity to “implement, interpret and prescribe” law and policy housed in institutions outside itself, Congress would be unable to respond effectively, if at all, to the public’s desire for action. If, as some would have it, our elected representatives were required to hone every law they enact into a form that could be put in effect with no subsequent adjustments by responsible officials in executive branch or independent agencies, there would be precious few laws of any import.^[4] One example will illustrate the magnitude of the actual law-making task. When it was last amended more than a decade ago, the Clean Air Act was widely considered one of the longest and most detailed pieces of legislation ever crafted by Congress. However, once enacted, the Environmental Protection Agency was required to write literally hundreds of rules and regulations to give more precise, predictable meaning to the language of the statute for enforcement staff and regulated parties. This pattern, if not the scale of the rule-making task, is repeated with virtually every law enacted by the Congress.

Rulemaking allows our elected representatives to respond, with varying degrees of specificity, to the will of the people, routinely expressed in a blizzard of expectations presented to them by constituents and supplicants every term. The process by which Congress transfers the law-making power from itself to executive or independent agencies is “delegation.” When Congress delegates, it does so for reasons other than the sheer crush of public and private calls for legislative action. The technical complexity of the issues and

problems that are the object of Congressional legislation—ranging from stem cell research to the intricacies of telecommunications—routinely pushes decision makers to the edge of human knowledge and comprehension, or beyond. The necessary research and analysis is largely entrusted to the career civil service and contractors they manage, and it is the results of these inquiries that ultimately become the substance of rules and, therefore, our law. With workload and complexity, Congress also transfers political pressure. It has been long hypothesized that Congress frequently delegates responsibility for decisions to agencies when their consequences entail considerable political risk. When controversial issues are completely or partially unresolved by Congress and inherited by those who write rules, the affected interests do not disappear. They move to the agencies, monitoring their actions and drawing on a wide range of tools and tactics to influence the outcome of rulemaking. As we will note below, when the rulemakers issue their decisions, they are subject to oversight by the very Congress that initiated the process. So, when delegating the authority to write rules, Congress transfers a great deal more than a heavy workload.

The status of rulemaking as a device for public policy is rivaled in importance only by the profound threat it poses in the minds of some to the very fabric of our constitutional democracy. It is certainly true that Article 1, Section 1 of the Constitution of the United States, the first pronouncement made by the founders about the structure and process of our particular democracy, states that “All legislative powers herein granted will be vested in a Congress, consisting of a House of Representatives and a Senate.” The reader will note that the Founders did not add to the components of the Congress, for example, the Nuclear Regulatory Commission or the Environmental Protection Agency. So, the Constitution would appear to foreclose the process of delegation and the vesting of the law-making power in the form of rulemaking. Clearly, what is missing to the critics of rulemaking is the strong and direct link between the writing of law and the people affected by it that is provided by the electoral process. There is no doubt that the Founders considered lawmaking the most important power and vested it in a body at least somewhat resistant to the suspected antidemocratic tendencies of executives and judges known at the time. Obviously, the Republic has survived with rulemaking firmly in place for most of our history, and the Supreme Court, despite the apparently absolute language in the Constitution has, on all but one occasion, rejected arguments that this form of delegation is illicit and a corrosive violation of basic democratic principles. We survive as a democratic system and rulemaking has emerged from the harsh light of the judicial scrutiny because the

Congress, more than a century and a half after authorizing rulemaking for the first time, fashioned an acceptable process to write rules that Professor Davis contends “can be, when the agency so desires, a virtual duplicate of the legislative process.”^[3] That approach to rulemaking is now embedded in the basic architecture of the administrative process.

THE RULE-MAKING PROCESS

Before turning to that process it is important to review what rulemaking currently produces to convey the magnitude of its importance to our political and legal system. The traditional way to measure the extent of rule-making activity is to simply count the number of rules published yearly in the *Federal Register*. The *Federal Register* was created by Congress to serve as a daily compendium of actions taken by agencies of the federal government.^[5] By this yardstick, rule-making activity has waxed and waned somewhat over the past, but the volume has been high by any standard. For example, the high water mark for final and proposed rules, until the end of the Clinton administration, was in 1980, the final year of the Carter presidency. In that year, more than 13,000 rules appeared in the *Federal Register*. Since that time, the fewest number of rules published was in 1997. Throughout the period, the number has mainly remained in the 7000 to 8000 rule range. The number of rules written by agencies in a given year tells us little about the impact they have on the lives and activities they affect. Among other things, rules establish the requirements that are enforced in our many and varied regulatory programs. The actual costs and benefits arising from the operation of regulatory programs are determined to a considerable extent by the rules, and for the last several years, we have had official estimates of these forms of effect. In a report on their findings, the Office of Regulatory and Information Affairs in the Office of Management and Budget set the ranges of costs and benefits in dollars incurred as a result of compliance with regulation at between 254 billion and 1.8 trillion and 146 and 229 billion, respectively.^[6] Although the uncertainty in the analysis is considerable and the ranges are obviously quite broad, if one takes the lowest estimates in both categories the effects of rules, positive and negative, are still enormous. When the stakes are this high, the process that establishes the winners and losers is obviously important, and will be the focal point of much attention.

The contemporary rule-making process has its origins in the APA of 1946. Debates about the need for and design of a statute that would provide operating instructions to administrative agencies for the conduct of their most important functions began well before the

World War II. Over time the deliberations took numerous twists and turns, and generated considerable controversy.^[5] As enacted, the APA considers various forms of rulemaking, but by far the most important is outlined in Section 553, and has come to be known as “notice and comment” or informal rulemaking.

In this basic design, the responsible agency is expected to publish its intentions with regard to a new rule or regulation in the *Federal Register*, allow the public to comment on the proposed action in writing and publish its final decision, also in the *Federal Register*, with an effective date. The APA provided little guidance beyond these skeletal requirements, but subsequent Congresses, presidents, and courts have put plenty of meat on its bones. The space allotted here is insufficient to even scratch the surface of the mountain of detail in statutes, executive actions, and court opinions that may affect the conduct of a given rule-making. In all this subsequent legal authority, the fundamental operating principles of the APA have been preserved. Virtually every pronouncement by a Congress, a president, or judges relate in some way to one or more of the three fundamental rule-making principles established in the APA: information, participation, and accountability.

Information, Participation, and Accountability

The conception of information found in the original APA was quite limited. The act did require prospective notification of the public of the rule-making action the agency was contemplating in the *Federal Register*, but a general description could substitute for the actual language being proposed. Since that time, the clear expectation expressed repeatedly by those with political and judicial influence, and the requirements of the agencies themselves and the *Federal Register*, is that the full text of the proposed rule be published in the *Federal Register*, accompanied by a preamble that outlines authority under which the action is taken and the basis for the actions. Following a period of public comment, a crucial element in the second basic operating principle of the rule-making process, the agency again informs the public through publication of the final rule in the *Federal Register*, again with a preamble that provides not only essential background information, but also summarizes the results of the public input that the earlier notice generated. The vehicles that agencies themselves use to transmit this essential information to the public have also diversified and increased in number, fueled by the rise of interest groups, as well as the recent revolution in electronic communication and the web.

Developments since passage of the APA with regard to the second principle of rulemaking, participation,

have been even more dramatic. This is both understandable and appropriate because participation by the public in the writing of rules is, in effect, the surrogate for the democratic function served by the electoral process in legislation. It is what has led to Professor Davis's conclusion, expressed above, that rulemaking can be a more than an acceptable substitute for the legislative process. Like information, the level and type of participation established in the APA was limited, and there were no expressed guarantees that agency personnel would take what the public was expressing seriously. The act required agencies to solicit and receive oral or written comments at their discretion; it did not specify (or even mention) what the responsible officials were to do with the information once it was in hand. Since then, the forms of participation, and the expectations with regard to agencies' uses of what the public provides, have changed dramatically, and again the rise of interest groups has fueled many of these developments.

In addition to written comment, we know from survey work that interest groups closely monitor rule-making activity and engage in a variety of activities to influence agency decisions. Among the more prominent is the development of grassroots campaigns to increase the volume and intensity of public comments, coalition formation to develop allies in the campaign to influence the rule, and “informal” contacts with agency personnel prior to publication of proposed and final rules.^[5] It should also be noted that interest groups report relatively high levels of success in getting what they want from rule-making processes. This not surprising since agencies are now expected to take what they hear from the public seriously, to the extent that in the mandatory preambles of final rules the agency is expected to summarize the data and views received from the public, as well as explain how the original proposal has changed in light of the new information. The most extensive form of public participation, and one where the input of the public can be most influential, is negotiated rulemaking, which is discussed in the subsequent section.

The third fundamental principle that anchors the entire rule-making process is accountability, or the expectation that those who write rules may be questioned about and held responsible for their actions. The sole form of accountability mentioned in the APA is judicial review that grants the public the right to sue an agency if it violated procedures during the course of a rulemaking or issued a rule that constitutes an “arbitrary or capricious abuse of discretion.”^[7] Since passage of the act, the courts have virtually opened their doors to those seeking relief from rules and this form of accountability remains robust. The act does not explicitly mention the many mechanisms of accountability, some long-established, others more

recent, that are exercised by Congress and the president. The president has always appointed the leadership of agencies that write rules, submitted most of their budgets to Congress and supervised the agencies through executive orders and general management authority. The traditional powers of the purse, oversight, legislation, and approval of appointments have always been the purview of Congress. However, the president and the Congress have also fashioned instruments of accountability more finely tuned and focused on the rule-making process.

The Carter administration instituted a system of senior management involvement in the setting of rule-making priorities. Far more aggressive and significant was the system of White House review of all proposed and final rules instituted by President Reagan, which has been refined by each president since then. In addition, presidents have routinely issued statements of "regulatory principles" to guide those writing rules. Congress came late to this party. They enacted the Regulatory Flexibility Act as a new section in Title 5 of the U.S. Code where the APA is contained. It required agencies to analyze the effects of proposed rules on small businesses.^[8] Subsequently, they found the president's approach of microlevel review appealing. In 1996, they passed the Congressional Review Act that also amended Title 5 of the U.S. Code, requiring submission of rules to the General Accounting Office for a determination of its compliance with authorizing legislation with the option of enacting legislation to declare the rule null and void.^[5] The Congressional Review Act was a much delayed response to the Supreme Court's repudiation of the "legislative veto" that existed in various forms until it was invalidated in 1983.^[9] Although the powers of the Congressional Review Act are substantial, they have been used only once since its enactment in the early months of the Bush administration, when legislation passed and signed by the president undid the ergonomics rule issued by the Occupational Safety and Health Administration of the Department of Labor. Used or unused, the mechanisms of accountability currently available to the Congress, the president, and the courts are now so extensive that those writing rules must anticipate issues and concerns arising in these branches if the products of their rulemakings are to survive.

The rule-making process that has evolved from both the development and interaction of these three fundamental principles is now highly complex. Scholars have established that a contemporary rulemaking can pass through as many as a dozen stages of development, ranging from the authorization to begin a rule-making project, planning and securing the resources needed to complete the work, proceeding to the collection of essential information and policy guidance to develop a draft proposal and final rule, and the

multiple levels and types of review to which the product will be subjected.

RECENT RULE-MAKING REFORMS

In an effort to improve the process and content of rules, and to increase chances that it will succeed in accomplishing their varied purposes, agencies now have numerous tools at their disposal. Among the most prominent of these is the use of various outreach and consensus building techniques to improve both content and acceptability; the application of the principles of cost-benefit and risk analysis to determine the need for, and best approaches to, regulations under development and employment of information; and advanced communications technology to provide the public with essential information and to facilitate participation in the process.

Negotiated rulemaking is a form of consensual decision making that essentially transfers the concept of collective bargaining and the principles of consensual process to the development of rules. It has been used only sparingly, and there is significant controversy over its effectiveness and efficiency, but available research does show that those who participate in negotiated rulemaking rate the process and its results as superior to other techniques. Participants also report a deeper understanding for the complexities of the public policy process and a better appreciation for the positions of their adversaries.^[10]

The use of cost-benefit and risk analyses in rule-making spans several decades, but they have been given renewed emphasis in the current Bush administration. Risk analysis promotes an understanding of the dangers associated with various activities and situations and a strong priority-setting process for agencies. Cost-benefit analysis can build on risk analysis by providing estimates of the price to be paid under various potential interventions to solve perceived problems, as well as provide a value for the public and private good that the regulatory action will produce.

Electronic tools have revolutionized the creation, transmission, storage, retrieval, and use of rule-making information. Virtually all agencies are currently engaged at some level with the use of electronic resources to facilitate and make for efficient or effective participation and management of rulemaking.

A good case can be made that rulemaking is the most important source of lawmaking. Until the tragedy and outrage of September 11 was visited on the United States, the major public policy issues on our agenda were all domestic, and with no exception, they would ultimately be resolved through rulemaking. From stem cell research to arsenic in water to reform of social security, rulemaking will be the primary

source of guidance to the public on their rights and obligations under the law. These are but the latest in a virtually endless stream of issues and problems that have been delegated to agencies. Given the wellsprings of our politics and the inherent limitations and proclivities of our institutions, rulemaking will be ascendant until the policy process changes in some fundamental way.

INTRODUCTION

Rural economic development remains an elusive field to all but a handful of experts and specialists. Novices and generalists often harbor misperceptions about rural places and their redevelopment. A few misconceptions are as follows: 1) rural places are economically, socially, or politically homogeneous, or nearly so, so that they share common circumstances, problems, and prospects; 2) rural places have a few comparative advantages—such as inexpensive labor and extensive undeveloped land resources—but have major disadvantages or deficits—such as remoteness from markets, sparse populations, uneducated workforces, and shortages of capital—that narrow economic development options; 3) widespread consensus about how to help rural places exists, but carefully executed, targeted policies are needed; and 4) rural economic development policy and practice placed in ways that benefit people most.

at economic growth from 1980 to 1993 in an effort to assess diversity in the rural heartland (see Table 1).

Federal Reserve researchers found that winners (high-growth) and losers (decline) were composed of very different county types. Losers likely had concentrations of farming and trade-dominated counties, whereas winners were more likely to be government, retirement, and mixed-use counties. In part, this reflects the remnants of the farm crisis in the late 1980s and early 1990s. Adjacent, larger population, rural counties tended to grow at greater rates than non-adjacent, smaller population rural counties. Adjacent counties likely shared economic growth factors with urban areas without becoming, as yet, urban areas.

Even though it may make sense to talk about differences in prosperity between county types, there are also considerable differences within county categories. From a public policy perspective, this makes targeting federal/state economic development aid or programs problematic. Each county should be examined on its own merits.

HETEROGENEITY OF RURAL PLACES

The U.S. Department of Agriculture's (USDA's) Economic Research Service defines rural areas as places, incorporated or unincorporated, with fewer than 2500 residents and open territory. About one-fourth of the U.S. population lives in rural areas. About one-fourth of rural counties are dominated by farming (see Table 1). One-third are trade intensive, and only 3% represent mining. Manufacturing, government, retirement, and mixed-use counties each account for about 6% of concentrations.

COMPARATIVE ADVANTAGES AND DISADVANTAGES

The Federal Reserve Bank of Kansas City combined economic use, population, and proximity indicators for 779 rural counties in 12 states, then they looked

ABSENCE OF A CONSENSUS ON POLICY

National Rural Policy

Farm interests are effective in articulating and realizing their agendas nationally and regionally. A national farm policy has guided agriculture throughout the century. Farmers want and receive credit usually through the Farm Credit Bureau and crop price subsidies through the USDA. Only under the Clinton administration in the 1990s have farmers been less successful in winning policy battles with environmental interests, concerned about wetlands, fertilizer runoffs, and land preservation.

With the exception of a coherent farm policy, no consistent voice represents rural America's interests in the national rural development policy arena. Beth Honadle, policy maker at USDA for nearly 20 years, offers an example. In the late 1980s, four powerful associations—National Association of Towns and

Table 1 Economic winners and losers in rural counties, 1980–1993, 10th Federal Reserve District

Townships, National Association of Counties, National Association of Regional Councils, and National Association of Development Organizations—tried to come together to lobby Congress and the administration for a national rural economic development policy, but nothing came of the effort because the associations could not agree on much.^[1]

Successive congresses and administrations have been divided on rural policy.^[2] Although it might appear that the USDA and its respective Congressional oversight committees determine rural economic development directions, they do not. A myriad of alphabet executive branch agencies—Small Business Administration, Rural Electrification Administration, Farmers Home Administration, Extension Service, Soil Conservation Service, U.S. Forest Service, Economic Development Administration, Department of Interior, and Environmental Protection Agency, not to mention the Appalachian Regional Commission, Tennessee Valley Authority, and Corps of Engineers—control bits and pieces of a larger pie. Each competes with overlapping jurisdictions, contradictory programs, and diverging visions for rural America.^[3–5] The U.S. Agency for International Development, for example, bolsters competitiveness of foreign firms, while the U.S. Commerce Department try to make American firms more competitive in world markets.

Locally, conflicts over policy objectives can be intense. At the heart of the issue are two, often conflicting, factors: preserving whatever makes rural life good and different from other places, while trying to address needs of poor people, flagging economies, declining populations and tax bases, and plant closings or military base shutdowns, on the one hand, or taking advantage of economic opportunity, on the other hand.

Ascendancy of one vision over another is not without consequence. Elderly retired people on fixed incomes in small towns suddenly find that rapid economic development so raises their property values that they cannot afford to live in the community, but are unable to leave. Some development of virgin land destroys it forever. Conversely, people in America's poorest regions—Indian reservations and the Mississippi Delta, for instance—may never benefit unless economic development is channeled their way, or once undeveloped rangelands become sites for gambling casinos developed by out-of-towners or Native American tribes. All conflicting visions and values.^[6]

EVOLVING ECONOMIC DEVELOPMENT POLICY AND PRACTICE

Federal, state, and local economic development policy and practice have evolved over the past three decades to address three epochs in an evolving rural America. The 1970s witnessed the "Rural Renaissance," a period of economic development and prosperity. The 1980s ushered in the farm crisis and decline of many rural places through population loss, declining income, increased poverty, and distress. The 1990s represented an era of differential prosperity and decline, depending on the region and local circumstances. Economic development strategies evolved from a focus on farming to industrial recruitment to entrepreneurship, although now most communities pursue all three simultaneously much as a stock investor diversifies a portfolio. Unhappily, policy and practice have yielded sparse results in many cases.

Industrial Recruitment

Rural industrial recruitment strategies focus on attracting branch plants of larger corporations, light manufacturing, distribution centers, and back office functions (e.g., low skilled data entry for banks), where officials believe they have a comparative advantage. Some rural communities chase high-technology companies and service businesses. The eight-county Mount Rogers Planning Commission in Virginia, for example, created a revolving loan fund (see section below) to attract high-tech companies—"brains over brawn" strategy. Officials in the Appalachian Regional Commission boast that every rural and distressed community is covered by a community college. Having access to colleges allows rural policy makers to replicate high-technology programs common at large, urban universities.

Public and private initiatives to attract outside industries are now seen by many to be wasted efforts.

There are just not enough industries willing to relocate or expand operations in rural places to make recruitment an effective strategy.

Entrepreneurship and Business Climate

Rather than devote so much effort to industrial recruitment, some rural places are trying to grow their own economies from within through entrepreneurship programs, small business incubators, entrepreneurship training, business technical assistance, export promotion, import substitution, business financing, and community marketing, especially in communities that believe they must help themselves or no one else will. Studies generally show that entrepreneurs participating in the programs value them, but many even in the smallest communities are unaware of their existence and do not seem to need them (e.g., Ref.^[7]). In earlier days, in the rush to foster entrepreneurship, organizations with little experience in the field began to work with entrepreneurs. Agricultural extension agents, community colleges, and even church groups (this is referred to as faith-based development) began to carve out a role. Although the assistance providers have, over the years, become more sophisticated in their approaches, in the late 1970s and early 1980s, many assistance programs were that in name only, handing out advice that was correct only by accident. Organizations have become more sophisticated. Now organizations—public, non-profit, and private—offering assistance in some rural places find themselves competing with one another, likely improving service quality.

Other initiatives focus mostly on improving business climate. This strategy creates a supportive environment for all entrepreneurs. It includes *deregulation*—eliminating needless or counterproductive regulations, *tax reduction*—lowering taxes businesses find oppressive, and *public service provision*—ensuring that education, health, safety, infrastructure, and utilities are effective, efficient, and of high quality.

Subsidizing Capital

Capital, in the form of debt or equity, drives rural economic development, especially entrepreneurship and local growth generally. However, analysts disagree about whether sufficient capital exists to meet demand.^[8] Those who hold that capital gaps or credit crunches widely exist in rural America believe that capital is scarce, costly, or problematic. Banks are conservative and lack competition. Equity investment is waiting.

The preponderance of empirical evidence suggests otherwise: *credit* markets effectively serve the needs of nearly all businesses in rural areas, or at least as well

as those in urban areas.^[9] Consider results of one representative study of entrepreneurs seeking bank financing across Idaho, Iowa, and Montana.^[10] Nearly three-fifths of entrepreneurs had bank loans. One-in-10 were turned down for loans, but only a handful of entrepreneurs were unable to eventually obtain bank financing.

Some analysts believe that as larger banks acquire smaller ones, credit availability in rural places will decrease. Results of studies on the impact of this trend are mixed. Some find that banks will take capital out of rural areas, reallocating it to more productive investments in cities. However, others see larger banks looking for growth and competing for more rural business, not less. Larger banks, having much more capital than small independents, actually make more credit available, not less. Banks now use computer credit scoring to evaluate loans, in effect making loans based on merit rather than “good ‘ole boy” networks that characterize rural lending by small banks.

Likewise, the few existing studies suggest that equity investment is widely available in most rural places. Brophy,^[11] in a study of equity investment in the form of venture capital and initial public stock offerings, found that rural areas do have access to venture capitalists and stock markets, even though these financial institutions may not be physically located near them. Entrepreneurs access equity capital in larger cities, serving rural areas. Using the Internet sites such as the Small Business Administration’s ACE-net, entrepreneurs and investors can link up in ways not possible even a few years ago.

Even though there appears to be ample capital, state and federal credit and equity capital programs abound.^[12] State and federal programs offer access to capital where it is unavailable and low interest or favorable terms where it is available—USDA’s Fund for Rural America, Business and Industry Program, Intermediary Re-lending Program, Rural Business Enterprise Grants, Rural Technology and Cooperative Development Grants, and Rural Economic Development Grants and Loans; SBA’s section 7a and 504 Programs; EDA’s Economic Adjustment Assistance Program; and Appalachian Regional Commission’s programs similar to USDA’s (see www.ag.ers.gov or www.arc.gov). In vogue are revolving loan funds in which a lender receives public monies to lend to business. When entrepreneurs repay loans, funds are re-lent. Lenders extract a fee for fund administration.

Another trend in public finance of private business are microcredit programs. Microbusinesses employ one or two people and generally have little growth potential, but they do employ those not employable elsewhere. Public programs provide small loans at favorable terms. Most operate as revolving loan funds. Many programs are subsidized, being unable to turn a profit. Because they focus on low growth, often

subsistence-based microbusinesses, programs do not much affect local economies. For many public officials, they may be more symbolic than economic.

Networking

Some rural economies may lack growth and development opportunities because they cannot achieve critical mass to bring together financial, technical support and educational institutions, and, most important, clusters or concentrations of similar industries that share these institutions. Although numerous networking and clustering initiatives are underway, assessments suggest that they have not “completely overcome the weaknesses of inadequately trained or financed entrepreneurs, the disadvantages of distance from market centers, or the limitations of small-scale entrepreneurs” (Sommers, 1998: 66).

Home-Based Businesses

Economic development strategists consider promotion of home-based businesses as a viable revitalization initiative. Policy makers provide incentives for people in rural areas to work out of their homes, including rezoning; influencing credit unions, banks, and other lenders; and creating small business “incubators without walls.” The “discovery” of home-based businesses seems rather strange. In fact, rural economies rely and have always relied on home-based businesses to a large extent: “old wine in new bottles.”

Telecommunications

The telecommunications revolution, stimulated by the Telecommunications Act of 1996 and revised regulations from the Federal Communications Commission in 1997, may eventually lead to development opportunities for rural places. Firms can cluster or network (see above) without having to be in the same geographic location. Buying and selling goods and services is greatly enhanced by the Internet. Having access to telecommunications of all kinds leads to innovation and new product development. Rural populations may become part of a workforce electronically, staying at home rather than leaving the community for work. Yet, many rural places will be slow to seize opportunities. Lack of competition arising out of small markets inhibits the development of first-rate telecommunications infrastructure and services, causing some commentators to call for publicly owned telecom enterprise. Given the track record of public enterprises (e.g., TVA teetering on insolvency), this may not be a viable solution.

Enterprise Zones/Enterprise Communities and Community Development Financial Institutions

Economic strategies discussed thus far intersect in the new \$1 billion Enterprise Zone/Enterprise Community (EZ/ECs) program and Community Development Financial Institutions. The Clinton administration designated three rural EZs and 30 rural ECs in 1994 from among 227 applicants (Reeder, 1997). The Bush administration has continued the program. Designation as an EZ or EC makes communities eligible for all types of federal aid, in addition to whatever states may channel to designees. Unlike EZs under past administrations, new ones combine economic development with social services. The three EZs are eligible for \$40 million in Social Service Block Grants each, and ECs for nearly \$3 million each. The USDA also targeted an additional \$50 million annually to the EZ/EC areas for infrastructure and business assistance. Each area is eligible for federal tax breaks, relief from government regulation, and other incentives.

In 1997, the Clinton administration added a program comparable to the EZ/EC initiative, the Rural Economic Area Partnership (REAP) to assist rural places in the Northern Great Plains. Recently, North Dakota received REAP designations for two zones. Funding under REAP is used to develop plans, then implement them. North Dakota created a revolving loan fund. Earlier in 1996, the Clinton administration created the Community Development Financial Institutions (CDFI) program for distressed communities, funded at about \$50 million annually. Selected financial institutions—banks, credit unions, loan or venture capital funds—interested in community development receive subsidies and incentives to invest in distressed areas: first-time home buyer mortgages, rental housing rehab, startup business loans, and bank services for low-income people. Ten CDFIs serve rural places.

These programs in turn parallel the 1994 Northwest Economic Adjustment Initiative, a \$1.2 billion, 5-year finance and technical assistance program for businesses, workers, tribes, and communities hurt by reduced federal timber harvesting in California, Oregon, and Washington. This program also promotes development partnerships.

Although focusing on distressed communities is laudable, evaluations of similar programs show only isolated success. Zones performed no better, and in some cases worse, than comparable areas without zones. Business is not attracted from outside distressed communities, leading to new jobs and employment. Rather, local businesses simply move into zones to take advantage of incentives. Zone businesses tend to hire workers, then take advantage of incentives; in other words, incentives compensate business for what

they would have done anyway. Combining economic and social policy has not worked in many places. Small businesses are jeopardized when forced to hire some zone residents who do not want to work, have no work experience, are uneducated, and may have a host of social problems. In addition to poor performance, rural EZ/ECs have been slow in getting underway because of bureaucratic red tape, unclear federal regulations, and contradictory policy directions.^[13]

PARTNERSHIPS AND COLLABORATION

In a previous section, fragmentation of rural economic development interests was presented. It surprises no one, therefore, that a major thrust of rural economic development policy would be for government—at all levels—to try to undo negative effects of fragmentation by creating organizations to overcome it.^[12] The Reagan administration created Rural Enterprise Teams as a way of partnering the USDA and other alphabet agencies—about 60 in all—with state-level economic development agencies to pursue pilot projects. The Office of Rural Development Policy coordinated rural economic development, but was eventually defunded for ineffectiveness. Under the Bush administration in 1990, State Rural Development Councils, having an executive director and staff, work as liaisons between governor's offices and federal agencies, as part of the National Rural Development Partnership (Radin, 1997). As of 1997, 39 states created councils. Councils working with the partnership formulate “action plans,” not policy, to be pursued in a consensus-building process. Bush also appointed a Council on Rural America, whose report, *Revitalizing Rural America Through Collaboration*, recommended creating an advisory council, a senior advisor, and a policy coordinating groups to foster collaboration. The White House staff ignored the report, fearing creation of yet another organization.^[1]

The Clinton administration also supported the National Rural Development Partnership and state councils, and even added another variation in 1993—President's Council on Sustainable Development. Although the council is not exclusively rural, it has a rural taskforce, the Pacific Northwest Council, imbedded in its structure. In its report, *Sustainable America*, the council calls for economic development activities that protect the environment, such as ecoindustrial parks. The council employs a multistakeholder process, but has little program or money. The council wants to create a National Sustainable Development Extension Network to educate, train, publicize, and transfer technology for sustainable development.

The track record of these approaches is mixed, at best (Radin, 1997). Many initiatives added a new layer

of bureaucracy to an already crowded field. Initiatives duplicated existing organizations in some states, furthering, rather than reducing, competition and fragmentation. Initiatives focused so much on process that they sometimes failed to do anything substantive, either because the parties could not agree or the process went on so long that participants lost interest. Initiatives have few resources, minimizing impact. The most salient criticism is that these approaches simply assume a problem and then provide funding to entice states and regions to participate. They do not allow states and regions to define problems and devise their own solutions, then provide funding in support. Consequently, states and regions are independently developing their own innovative approaches, such as Oklahoma Futures; Kansas, Inc.; or Greater Minnesota Corporation of the bilateral Red River Trade Corridor, serving Minnesota, North Dakota, South Dakota, and Canada's Manitoba Province, to solve coordination and resource allocation problems.

PEOPLE, PLACES, AND ECONOMIC DEVELOPMENT

At the heart of rural economic development is whether to invest scarce resources in places or people. Nearly all rural economic development policy is place based. Its intent appears to be to keep people in rural locations, hoping that they can grow their economies, rather than abandon them. The National Commission on Agriculture and Rural Development Policy made this explicit. Two goals of rural policy are: “Rural areas and people must be economically self-reliant,” and “Rural areas and people must be able to adapt to change” (1990: 6). Building industrial parks, recruiting industry, supporting entrepreneurship, developing infrastructure, and improving housing and the like are place-based strategies because they help only if people reside in rural places where investment are made. Even training or retraining programs are place based in the sense that they train people for possible jobs in the area.

Some place-based strategies may work well to be sure, but others clearly have not. There are still large pockets of rural poverty—poverty counties—in the Mississippi Delta, throughout many states in Appalachia, and on Indian reservations, in spite of the billions spent over the decades to make them better places to live. One reason why pockets of poverty remain is that even after continuing heavy public investment, these rural places still lack sustainable competitive advantages over other places. So public subsidies hold many people in place without making their lives better.

There are some exceptions worth noting. Lower transportation costs originating from containerization,

deregulation, and computer linkages; telecommunications allowing instant data transfer; and multisourcing of materials—many rather than one source of supply—have reduced the “rurality” and remoteness problem in rural economies.

Rural Health Policy

Esther M. Forti

Department of Health Professions, Medical University of South Carolina,
Charleston, South Carolina, U.S.A.

INTRODUCTION

Health care in America has undergone tremendous changes since the 1980s and continues to change. Rural areas are still struggling with inequitable payment systems for services, instability of many small rural hospitals, continued shortage of health care professionals, and low population density to support many needed services and managed care systems. Thus, the health care needs of rural residents are still not being met at the same level as those in more urban areas. Given the scarcity of resources in rural areas, no rural community can be totally self-sufficient in meeting the health care needs of its population. Demographic, political, social, cultural, and economic changes are different for rural than for urban populations, yet health policy does not always recognize these differences.

Policy decisions frequently address urban needs and problems and are usually informed by urban research. The voices of rural policy makers have a tendency to be lost in national policy. When policies are implemented that do not consider diversity in rural, and rural and urban, differences, problems in rural areas remain unsolved with the potential of urban-based policies being detrimental to the rural health care system. For example, lower Medicare payments to rural hospitals led to increases in hospital closures in the 1980s. Moreover, the national policy focus on lowering costs of health care through competition has not been favorable to the ongoing needs of rural health. In light of these events, it is crucial that the policy community be cognizant of and employ available and relevant rural research findings to inform health policy debate processes on the national and local levels.^[1] The goals of this article are to provide an overview of the issues that affect the rural health care system, describe selected rural health policy priority issues, and propose policy recommendations to create a viable rural health care system.

BACKGROUND

In the 1980s, rural advocates talked about a health care “crisis” in rural America. Policies and programs administered by federal agencies did not consider differences in rural and urban areas. The federal government is developing mechanisms to address rural

health concerns. The National Advisory Committee on Rural Health, comprised of nationally recognized rural health experts, was chartered in 1987 to advise the secretary of the Department of Health and Human Services (DHHS) on strategies to address the health care in rural America. The Office of Rural Health Policy (ORHP), also established in late 1987, provides a voice for rural health policy advocacy, information, and grant programs. The office works within the federal government, and in the private sector with associations, providers, and community leaders to solve problems and seek assistance in meeting rural health needs. One focus of the ORHP was the initiation of several grant programs to address rural health deficits. Two of these programs, Outreach and Network Development grants, focus on increasing access to care, as well as coordinating and improving the quality of health care in rural communities. Grants to states include the State Offices of Rural Health (SORH) program and the Rural Hospital Flexibility program. The SORH program, initiated in 1991, provides matching funds to states to help rural communities build viable health care systems. The Rural Hospital Flexibility program was initiated in 1999 to provide funding to state governments to strengthen rural health by allowing small rural hospitals the flexibility to reconfigure their operations and be licensed as critical care hospitals.^[2]

Another program under the direction of the Health Resources and Services Administration is the 1996 Health Centers Consolidated Act. This program provides funds for community health centers (CHCs), migrant health centers, health care for the homeless, and primary care for public housing residents. The CHCs, known as one of the safety net provider systems, assume responsibility for the primary and preventive health care needs of the increasing number of uninsured and vulnerable populations that reside in rural and medically underserved areas.^[3]

SELECTED POLICY ISSUES AND RECOMMENDATIONS

Policy issues surrounding rural health care needs are linked closely to national health care concerns, especially with regard to resources such as access to care, caring for the uninsured, health professions

workforce, defining rural for public programs, and reimbursement structures.

Access to Care

Rural health policy has historically focused, and continues to focus, on problems with access to care. Factors associated with the rural environment that affect access to health care are scarce resources, diversity among rural communities, fragile economies, high poverty rates with high unemployment and underemployment, lack of adequate transportation systems, higher percentage of uninsured or underinsured, fragile rural hospitals, an increase in the number of elderly people (e.g., high dependency ratio), and shifts in population with outmigration. Population shifts are important to understand because they result in a low unstable population base that contributes to an inability of rural communities to sustain adequate health services and infrastructures. Small rural hospitals are more likely to survive by becoming diverse in providing essential services to their communities. Outpatient services, Medicare swing-bed programs, long-term care facilities, home health care services, hospice care, urgent care centers, satellite clinics, multi-hospital arrangements, managed care systems, and critical access designations are several alternate delivery options available to small community hospitals.^[4]

Policy recommendations are to continue to work to ensure that rural people have access to quality health care by strengthening the rural infrastructure through public programs for the safety net provider systems, creating rural health networks, workforce development, and equitable reimbursement systems. Also, it is important to continue to provide funds and technical assistance to small rural hospitals to enable them to diversify services and join health care networks, and to devise innovative community-driven strategies to strengthen rural transportation systems.

Rural Uninsured

There has been a substantial rise in the number of uninsured over the past several years. Rural persons are more likely to be uninsured than those living in more urban areas. Moreover, there are notable differences between the rural and urban uninsured. Rural persons are more likely to rely on private insurance plans because they work for small employers, are self-employed (e.g., farmers), or are underemployed. In addition, rural workers are more likely to have incomes less than 100% below the poverty level than urban workers. Policy intervention will most likely require public investment.^[5]

Policy recommendations are to remember that policy formulations need to be sensitive to the low incomes of rural residents, and strategies need to be devised to aggregate large groups of similarly insured persons because large employers are not common in rural settings.

Shortage of Health Professionals

Despite the fact that rural residents report poorer health and have higher rates of chronic diseases, there exists a shortage of health professionals to serve these health needs. Initiatives developed to address health manpower shortages in rural underserved areas include the National Health Service Corps (NHSC) and federally designated Health Professional Shortage Areas (HPSAs). The NHSC was established in 1972 in response to the shortage of health manpower and inadequate access to health services in rural and urban poverty areas. Legislation was passed to enable students to obtain scholarships for training costs in return for field service or loan repayment to already trained primary care clinicians and matching these candidates to communities in need of their services.^[3]

Also, the federal government designated HPSAs and Medically Underserved Areas (MUAs) to address the shortage of health professionals in rural areas. The DHHS recommends a ratio of one primary care physician to every 2000 residents and designates medically underserved as those falling outside this recommendation. In many rural areas, this ratio translates into one physician for every 3500 residents. These designated shortage areas receive federally subsidized monies in an attempt to correct such shortages.^[6] However, it is difficult to retain physicians in rural practices because of professional isolation, lower salaries and reimbursement structures, poor school systems, inability for spousal employment, and longer work hours.^[7]

Policy recommendations are to continue and increase funding for the NHSC program; to train and educate health professionals in rural community-based settings to increase the potential of health professionals choosing and practicing in these communities; and to use non-physician providers (physician assistants, nurse practitioner, nurse midwives) to address the shortage of primary care physicians. State Practice Acts need to be examined and revised to allow reimbursement to non-physician providers for providing primary care health services in rural communities.

Defining Rural for Public Programs

One of the policy issues of major interest is the continued lack of a uniform definition for what is rural. The need for precision in defining rural has escalated

because today's rural America is much more diverse than yesterday's and the needs continue to grow. The topologies most commonly used are rural-urban or metropolitan-non-metropolitan dichotomous groupings. Data are often collected at the county level that bypass small, remote rural communities. Further, rural and non-metropolitan are not synonymous. For example, non-metropolitan areas include urban populations (small cities), and Metropolitan Statistical Areas (MSAs) contain portions of rural populations. Such crude dichotomous coding of residence makes identification of diversity across rural difficult and complicates the implementation of federal policy designated to meet the health care needs of rural residents. Adding further to the confusion, values defining areas as rural are diverse and varied from one government agency to another.^[8]

One policy recommendation is to continue to identify various typologies to address diversity in rural settings and to assist policy makers in choosing a definition that will match need with program.

Rural Reimbursement Structures

Rural physicians rely more heavily than urban physicians on rates of reimbursement from public entitlement programs, such as Medicaid and Medicare. From the inception of these entitlement programs, the system of payment was lower for rural areas based on the assumption that rural areas had lower costs and a lower wage index. These lower payments have had a negative impact on the survival of rural hospitals and retention of physicians. In addition, the dependency ratio is high in rural areas because of the increasing number of elderly people. Medicare reform is a current topic of debate, and much activity is being put forth to redesign the system. Medicare proposals are spread across a continuum from a government-financed system at one end to a system whereby the government supports private health plans. Medicare payment policies are designed to reward market-based efficiency and cost containment. These policy proposals do not consider that rural areas have low-volume providers with fixed costs, decreased access to health care professionals, and persons with poorer health conditions. These rural characteristics place beneficiaries at risk in a market-driven Medicare redesign system.^[9]

Medicaid is a government-sponsored health insurance program for eligible persons. States determine the eligibility requirements and receive federal dollars based on indicators of need. Many states use Medicaid managed care programs. Medicaid managed care reimbursement models offered to providers range from a case management fee and a fee-for-service basis to a

reimbursement system that provides a fixed monthly per capita rate. The type of program offered in rural areas depends on its proximity to urban centers. Urban centers were much more likely to receive fully capitated programs. However, there has been a reluctance on the part of managed care organizations to provide services to rural areas because of low population density and a lack of appropriately credentialed health care providers such as non-physician practitioners. However, some states have offered flexibility in program eligibility. For example, a wide range of providers were allowed to function as primary care case managers. They also allowed emergency rooms to provide care after hours in rural communities with limited practitioners to share on call.^[10]

Policy recommendations are to redesign the Medicare reimbursement structure to ensure that Medicare beneficiaries have access to needed care in rural settings where payments need to approximate the costs that providers would incur in furnishing high quality care; to redesign Medicare to ensure that quality of care is monitored through standardized measures that are used across managed care and fee-for-service systems; and to have states continue to show flexibility in program requirements.

CONCLUSION

This article provided an overview of the relevant issues related to rural health care and describes trends and recommendations to address several of the problems plaguing rural America. It is essential that federal and state public programs consider rural in their policy decisions. The political milieu, demographics of rural settings, population density as related to services, and diversity among rural communities must be considered in health policy decisions to adequately address the health care needs of rural residents.

The future of rural health relies on a system of networks staffed by health professionals who have been trained in an interdisciplinary manner to meet the unique needs of a diverse rural America. Survival mandates that rural communities accept ownership, develop innovative alternate delivery systems, telecommunication systems, and integrated rural health networks to enhance their health care systems and to provide comprehensive health services to its populations. Solving the problems in our rural health care system is a challenge of balancing broad public policy with focused local needs. As Tilly, a rural sociologist, contended, when threatened communities do act because rural people have a long-standing tradition of coming together to solve their problems.^[11] Finally, a report on rural health defined one vision statement as, "Rural Communities share in the responsibility

for a healthy nation and the nation shares in the responsibility for a healthy rural America.’’^[12]

Science of Administration

Mark R. Rutgers

Department of Public Administration, Leiden University,
Leiden, The Netherlands

INTRODUCTION

The science of administration can be characterized as the systematic or methodologically guided attempt to describe, understand, and/or explain the workings of administration. Administration concerns the mobilization and organization of men and materials to develop and execute specific social goals (i.e., policies). This description can be further specified by indicating that the science of administration is concerned with *public* administration. It is an applied field of study that brings together or integrates knowledge on public administration developed in a wide array of other fields (i.e., it is an interdisciplinary science). There is, however, no consensus on the meaning of “science of administration” because the meaning of “science” and “administration” is a topic of dispute.

DEFINITION OF ADMINISTRATION

Science of administration is used in three different ways: historical, ontological, and methodological. The three different references to a science of administration are intertwined, but can be at odds.

When used to indicate an *historical* episode, science of administration refers to the approach to studying public administration as practiced by American authors in between roughly 1910 and 1940. The idea was that a science of administration would discover universal principles of administration. This period can also be referred to as pre-World War II public administration, or administrative orthodoxy. In this meaning, the science of administration is opposed to post-World War II developments in the study of public administration.

In an *ontological* sense, science of administration is used to indicate that the object of study—administrative reality—is a uniform, monomorphous phenomenon. The science of administration is then put forward as the general study of administration. It opposes the convention that the science of administration has as its object of study (just) public administration. From a scientific perspective, it is considered irrelevant or secondary to distinguish between business (profit) and public (non- and not-for-profit) administration.

Debates on limiting or broadening the object of study of the science of administration have resulted in, for example, arguments to focus on public policy or public management, or to expand the scope to human decision making or governance.

As a *methodological* statement, the reference to a science of administration is used to claim a specific approach (i.e., method) for studying administrative phenomena. Usually it implies that a distinction can be made between a scientific approach and the art, study, practice, and/or profession of administration. Again and again, authors have claimed to provide the proper (i.e., scientific) approach to studying (public) administration contrary to their forerunners. In the second half of the twentieth century, the reference to a science of administration is generally associated with the ideas of Herbert Simon, who argued a logical-positivistic approach. The question as to whether the study of (public) administration is, should be, or can be regarded as a science ultimately depends on the ideas on what constitutes a (social) science. The views on science and on human knowledge in general also determine the meaning (and acceptability) of characterizations of the study in terms of paradigms, discipline, practical relevance, interdisciplinarity, and so on. Proponents and opponents of a scientific approach to administration can be grouped in accordance with the more general divide in the philosophy of the social sciences between nomothetic (or positivistic) and hermeneutic (or interpretative) methodologies.

Cultural Aspects

The debates on the scientific status of the study of public administration are influenced by more linguistic or cultural aspects. An example is the double use of public administration in English for denoting the study (science) and the object of study (social practice). This makes it difficult to keep the two apart in English, and authors are inclined to mix up the two. A common attempt to avoid this is to use capitals when referring to the study of public administration. Another example is the meaning of science. For instance, history, social studies, and the like are regarded as sciences in German because the meaning of *Wissenschaft* is not limited to the approach in the natural sciences.

Cultural differences are even more prominent in the conceptualization of the object of study. Public administration is the product of sociohistorical developments. Notably, the constitutional and legal context is of prime importance as to the specific nature and meaning of public administration in a social reality. For instance the nature of the relation between politics and administration can be very different in many respects. The precise meaning of public administration is very much culture and language specific. Thus the nature of “the separation of powers” may be interpreted differently, and there may be no equivalent concept available for policy, agency, or even administration in another language. Whether this is important for a science of administration again depends on the philosophy of the social science adhered to.

HISTORICAL DEVELOPMENTS

Cameralism to Positivism

The attempt to develop a specific science of administration dates back to the seventeenth century's development of council studies: *Cameralism* and *polity science*.^[1] The appointment of two university professors in Prussia in 1729 signals its formal beginning. Veit Ludwig von Seckendorff can, however, be considered the first administrative scientist due to his publication of *Teutscher Fürsten Staat* (1656), or *German Principality*.^[2] He described topics relevant to the administration of a small principality. Seckendorff called his work scientific because it is an attempt to transcend the uniqueness of everyday practice. The French author Delamare took a similar position in *Traité de la Police* (1703–1738), or *Treatise on Polity*.^[3] He crafted a science about public administration under a prince. Both books were primarily collections of historical, practical, and legal knowledge on the running of a state's administration. It was scientific according to contemporary standards.

Eighteenth-century scholars such as Justi and Sonnenfels were much more theoretically oriented. They took a contract theory of the state as their starting point and argued that the king or prince was supposed to provide happiness for its inhabitants by means of the state's administration or polity: “The polity is a science dealing with organization of the home administration of the state.”^[4]

With the rise of a more modern concept of science in the Enlightenment, we encounter the first attempts to establish a positivistic science of administration. The French author Bonnin's *Principe d'Administration Publique* (1812), or *Principle of Public Administration*, is one of the earliest.^[5] According to Bonnin,

public administration was an application-oriented science, balancing law and social studies. He wanted to model it on the positivistic natural sciences.

In the second half of the nineteenth century, the most prominent attempt to create an encompassing administrative science is by the German scholar Lorenz Von Stein (1815–1890). He regarded *Verwaltungslehre*, or the *Study of Administration*, the crown on all the sciences because it brings together all knowledge available to improving society by means of the state. Stein was one of the first to characterize the modern state as an administrative state.^[6] Despite Stein, a specific administrative science disappeared almost entirely from Europe. This was partly due to changing ideas about science, resulting in the removal of applied fields from the universities, as well as to the rise of liberal ideas on state and society, causing the old polity or police sciences to become reviled. The meaning of administration was narrowed to the execution of law and regarded a topic for lawyers, not for social scientists.

American Developments

In the United States, a science of administration developed in the early twentieth century in the slipstream of nineteenth-century ideas on the improvement of public ethics (the moral reform movement). Wilson's *The Study of Administration* (1887) is generally considered to be its first herald.^[7] Historically, Goodnow's *Politics and Administration* (1900), and the establishment of the New York Bureau of Municipal Research in 1906, can be considered the actual starting points of the science of administration in the United States.^[8] The ideal was a politically neutral, professional, morally impeccable, and performance-oriented state bureaucracy. Early American administrative thought was characterized by a strict normative distinction between political and administrative activities. This made it possible to regard public administration as the business of government and to treat public and business administration alike. There was a strong influence of Frederick Taylor's scientific management in the development of the science of administration. Also influential is Henry Fayol, who developed a general theory of administration by formulating principles of administration. Contrary to the natural sciences, there can be no laws of administration, he argued, as there will always be an amount of uncertainty involved.^[9] The search for universal administrative principles flourished in the 1920s and 1930s. There was the strong conviction that there are general principles of administration, and that their validity is universal and can be empirically validated.

Postwar Developments

In the post-World War II period, the American discourse became more divided. There was much criticism on the advancements, and the search for principles was broadly criticized. In particular, Herbert Simon and Dwight Waldo are associated with the search for new directions. In his *Administrative Behavior* (1947), Simon argued a logical-positivistic empirical science of decision making. The science of administration should focus on facts and refrain from value judgments.^[10] Almost to the opposite, in his *The Administrative State* (1948), Waldo stressed the specific political (i.e., valuation) nature of public administration and called for an interpretative and philosophical approach.^[11] He rejected the reduction of science to the methods of the natural sciences. Waldo started to refer to a “crisis of identity” in the study, a characterization that became widely acknowledged and is still influential.

In the second half of the twentieth century, the development of an autonomous science of (public) administration was picked up again in Europe. It relied heavily on U.S. ideas, but maintained (to the present day) a strong legal orientation and generally identified public administration as the state administration in a *Rechtsstaat*.

In the 1960s, public administrationists became split roughly along two dimensions: academic versus practice and research versus educational ideals. The academic-research-oriented administrationists pursued a positivist approach in the spirit of Herbert Simon. The focus was on decision making and organization studies. The academic-education-oriented group was primarily concerned with the development of the study in terms of a generalist curriculum, combining social sciences, history, comparative studies, and political theory. Here we find followers of Dwight Waldo. Although advocates of both camps were present in Europe, the prime concern was still the establishment of a social science perspective on public administration.

In the 1970s and 1980s, the multitude of alternative approaches to administration made a homogeneous view of the science of administration almost impossible. Nevertheless, the empirical study of public organizations and policies dominated the research agenda. More or less independent schools emerged. Some are characterized by a specific focus on (parts of) social reality, for instance, policy making or public management; others took a more specific (i.e., limited, theoretical, or methodological) orientation, such as rational choice theory or communicative theory. In Europe, this differentiation of the field was less because of the smaller number of scholars involved. At the same time, there was (and still is) a relatively

strong differentiation in national traditions in studying (public) administration.

In the 1980s and 1990s, the mainstream continued to focus on a practically relevant empirical study of public policy making and public management. The proliferation of alternative approaches to a science of administration, however, persisted to the degree that a diverse “refounding movement” established itself.^[12] Debates on the scientific status of the study resurfaced. Authors identified numerous sources for the “identity crisis,” and called for alternatives for understanding and improving public administration. Criticism on the scientific scrutiny of the study remain a recurring theme. The differences between authors still hinge on their perceptions of what constitutes a proper science, how study and practice should be related, and last but not least, how to conceptualize public administration. The latter topic has taken a new turn late twentieth, early twenty-first century as some authors argue “public administration” is too limited a concept and/or too closely associated with the machinery of government. They suggest that “governance” perhaps better captures the contemporary intertwinement of societal “steering” by both public and private organizations and administrations.^[13]

CONCLUSION

Since the mid-1600s, the need for scientific study of (public) administration has been acknowledged repeatedly. Both differentiation and integration of knowledge were advocated, normative foundations were disputed, and the need for a practitioner and/or academic orientation was (re)stated. There is an ongoing flip-flopping between limiting and specializing within the science of administration and attempts for synthesis and interdisciplinarity. Despite general acknowledgment of the existence of an impressive body of knowledge on public administration, the science of administration still does not have a well-defined identity or self-image in the early twenty-first century.
